Abstract

We consider the evolution of an incompressible two-dimensional perfect fluid as the boundary of its domain is deformed in a prescribed fashion. The flow is taken to be initially steady, and the boundary deformation is assumed to be slow compared to the fluid motion. The Eulerian flow is found to remain approximately steady throughout the evolution. At leading order, the velocity field depends instantaneously on the shape of the domain boundary, and it is determined by the steadiness and vorticity-preservation conditions. This is made explicit by reformulating the problem in terms of an area-preserving diffeomorphism g_Λ which transports the vorticity. The first-order correction to the velocity field is linear in the boundary velocity, and we show how it can be computed from the time-derivative of g_Λ.

The evolution of the Lagrangian position of fluid particles is also examined. Thanks to vorticity conservation, this position can be specified by an angle-like coordinate along vorticity contours. An evolution equation for this angle is derived, and the net change in angle resulting from a cyclic deformation of the domain boundary is calculated. This includes a geometric contribution which can be expressed as the integral of a certain curvature over the interior of the circuit that is traced by the parameters defining the deforming boundary.

A perturbation approach using Lie series is developed for the computation of both the Eulerian flow and geometric angle for small deformations of the boundary. Explicit results are presented for the evolution of nearly axisymmetric flows in slightly deformed discs.

1 Introduction

This paper examines the dynamics of a two-dimensional (2d) fluid inside a container whose boundary is deformed slowly. The fluid is assumed to be perfect and incompressible; consistent with the latter assumption, the area of the container is constant. Beyond potential applications such as the control of fluid flows, we use the problem as a paradigm for the study of Hamiltonian fluid models depending on slowly varying parameters. This is an obvious first step: the 2d Euler equations governing incompressible perfect fluids are indeed Hamiltonian (e.g., Morrison, 1998; Salmon, 1988), and imposing boundary deformations is arguably the most natural way of introducing a parameter dependence. As is well-known in finite dimensions, Hamiltonian systems are strongly constrained; as a result, slow changes of parameters lead to a remarkable behaviour encapsulated in the theory of adiabatic invariance (cf., e.g., Arnold, 1989; Landau and Lifshitz, 1960) and geometric angles (Hannay, 1985; Berry, 1985). In 2d Euler, the material invariance of vorticity (e.g., Saffman, 1992) similarly imposes a strong contraint on the system, which we exploit extensively to derive what can be interpreted as fluid-dynamical versions of adiabatic invariance and geometric angle.

The problem we consider here is rather involved in its full generality. To make progress, we make a number of assumptions and consider the following scenario. At an initial time, a steady flow is given in some simply-connected domain D_0. The streamlines have the simplest topology, that of nested closed curves, and the flow is Arnold stable (see section 2 below). We then assume that this continues to hold throughout the evolution as the domain is being deformed. With these hypotheses, we use an asymptotic approach, based on the separation between the timescales of the boundary deformation and that of the flow, to answer two questions: (i) what is the leading-order approximation to the (Eulerian) flow at any time; and (ii) what is the (Lagrangian) position of the fluid particles?

The first question is answered by showing that the leading-order flow is steady at all times. This makes it possible to rephrase the problem in terms of an area-preserving diffeomorphism g_Λ which maps the vorticity in the initial domain to the vorticity in the deformed domain. The uniqueness of g_Λ up to displacements along lines of constant vorticity, established in Wirosoetisno and Vanneste (2005; henceforth WV) and revisited here, shows that the leading-order velocity field is completely determined by the instantaneous shape of the boundary and is independent of the history of past shapes. This, of

course, is analogous to the adiabatic invariance of the action variables for finite-dimensional Hamiltonian systems with slowly varying parameters.

To answer the second question, we need to compute the first-order correction to the approximate velocity field obtained in (i). This is because the evolution equation for the particle position needs to be integrated over the long time scales required to achieve order-one boundary deformations. The first-order correction to the velocity field is linear in the boundary velocity, and it can be derived from $\mathrm{d}g_\Lambda/\mathrm{d}t$ by solving a pseudodifferential equation. Once this is done, the particle-position problem reduces to the solution of (independent) one-degree-of-freedom Hamiltonian systems with slowly varying parameters. Since particles remain on vorticity contours (which in effect are contours of constant action), only the position along each contour, regarded as an angle variable, needs to be determined. The value of this angle is found to depend on the history of the boundary shape. It includes a geometric contribution, similar to the Hannay–Berry angle, which possesses a nice interpretation (Hannay, 1985; Berry, 1985; Montgomery, 1988; Shapere and Wilczek, 1989a; Marsden et al., 1990). We note that the geometric angle has been studied in fluid dynamics by Shashikanth and Newton (1997, 1999) who considered point-vortex solutions of the 2d Euler equation, and by Shapere and Wilczek (1989b) for Stokes flow; here it appears in the context of smooth inviscid flows.

The determination of the leading-order Eulerian flow from the steadiness and vorticity-preservation conditions was treated in WV, where conditions for the existence of g_Λ and the uniqueness of the resulting velocity field were given in appropriate function spaces for sufficiently small boundary deformations. In the present article we adopt a more informal approach to treat both the Eulerian and Lagrangian problems under a slightly different set of hypotheses; rigorous proof of the adiabatic invariance will be the subject of a future work. It proves convenient to express our derivation in the language of differential forms in the space of the parameters defining the boundary shape. This makes explicit the linear dependence of several important quantities on the boundary velocity, and it gives a natural description of the geometric angle in terms of a curvature form in the parameter space. We use this language mainly as a notational tool, but it is clear that a more abstract geometric interpretation of the results could be given. This is discussed at the end of the paper.

In the following section, we present a short description of the 2d Euler equation in a deforming domain in order to fix the notation, and we consider the behaviour of the leading-order Eulerian flow. Next, in §3 we compute the first-order correction to the Eulerian flow, which depends only on the instantaneous shape of the boundary and its velocity. Using these results, we study the Lagrangian flow in §4, where the geometric angle of the particle position is derived. In these sections, we consider general domains and arbitrary boundary deformations, requiring only that the boundary deformation be slow. The

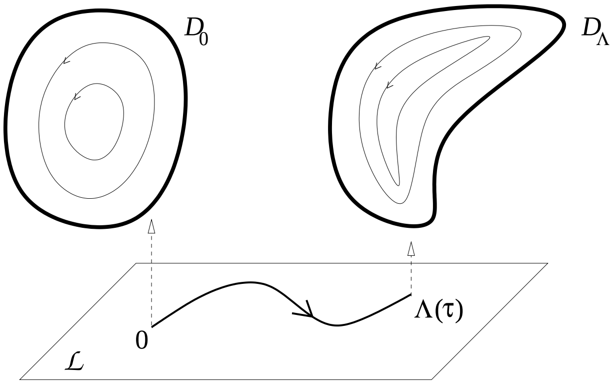

Fig. 1. Parameterization of the shape of the domain D_Λ by Λ: as the parameter Λ moves from $\Lambda(0) = 0$ to $\Lambda(\varepsilon t)$ in $\mathcal{L}$, the fluid's domain changes its shape from D_0 to D_Λ, inducing a change in the leading-order Eulerian flow whose streamlines are indicated.

results are given as solutions of partial (pseudo)differential equations, which in general will have to be solved numerically. In §5 we develop a perturbative approach for the solution of these equations, based on the assumption of small (total) boundary deformation. We carry out the calculation to second order, but the Lie series formulation that we employ is well suited for systematic extensions to higher orders. An application to nearly axisymmetric flows in a slightly deformed disc is presented in §6, followed by a Discussion. Technical details are relegated to the Appendices.

2 Eulerian Flow: Adiabatic Invariance

We begin by studying the behaviour of the Eulerian flow.

2.1 Formulation

Let $D_{\Lambda(\varepsilon t)} \subset \mathbb{R}^2$ be a simply-connected, bounded and smooth domain which is slowly evolving in time t in a prescribed fashion while keeping its area fixed. Here, Λ denotes the set of parameters defining the shape of the boundary, and the slowness of their time dependence is made explicit by the introduction of the asymptotic parameter $0 < \varepsilon \ll 1$. Denoting the (generally infinite-dimensional) space in which Λ lives by $\mathcal{L}$, we can think of the evolution of the domain shape as the tracing of a curve $\Lambda(\varepsilon t) \subset \mathcal{L}$; see Figure 1. In this article, our concern is the behaviour of the flow as $\varepsilon \to 0$, that is, in the limit of slow boundary deformation, over $O(\varepsilon^{-1})$ time scales so that $O(1)$ deformations are achieved. We make a blanket assumption that all functions are sufficiently smooth for our purposes, and we denote by $\mathcal{C}(D_\Lambda)$ the space of smooth real-valued functions in D_Λ.

We can describe the evolution of a perfect fluid flow in $D_{\Lambda(\varepsilon t)}$ using the vorticity–streamfunction formulation

$$\partial_t \omega + [\psi, \omega] = 0, \tag{2.1}$$
$$\omega = \Delta \psi. \tag{2.2}$$

The velocity is given by $(u, v) = \boldsymbol{\nabla}^\perp \psi := (-\partial_y \psi, \partial_x \psi)$, $\omega = \boldsymbol{\nabla}^\perp \cdot \boldsymbol{v} := \partial_x v - \partial_y u$ is the vorticity, and $[f, g] := \boldsymbol{\nabla}^\perp f \cdot \boldsymbol{\nabla} g = \partial_x f \, \partial_y g - \partial_x g \, \partial_y f$ is the Jacobian. Steady flows satisfy $[\psi, \omega] = 0$.

A convenient way of of defining the domain boundary $\partial D_{\Lambda(\varepsilon t)}$ is as the level set $B(x, y; \Lambda(\varepsilon t)) = 0$ of some prescribed function B. Since $\partial D_{\Lambda(\varepsilon t)}$ is a material curve,

$$\partial_t B + [\psi, B] = 0 \qquad \text{for } B(x, y; \Lambda(\varepsilon t)) = 0. \tag{2.3}$$

Assuming that $\boldsymbol{\nabla} B \neq 0$ on ∂D_Λ, this can be inverted to give the boundary condition

$$\psi = \varepsilon \, b(\varepsilon t) \qquad \text{on } \partial D_{\Lambda(\varepsilon t)}. \tag{2.4}$$

Since ψ is determined only up to an additive constant, we set

$$\oint_{\partial D_{\Lambda(\varepsilon t)}} b(\varepsilon t) \, \mathrm{d}l = 0. \tag{2.5}$$

It is clear from (2.3)–(2.4) that ψ is proportional to $\mathrm{d}\Lambda/\mathrm{d}t$ on ∂D_Λ.

Exploiting the smallness of ε, we expand the vorticity and streamfunction in ε,

$$\omega = \omega^{(0)} + \varepsilon \, \omega^{(1)} + \varepsilon^2 \omega^{(2)} + \cdots \quad \text{and} \quad \psi = \psi^{(0)} + \varepsilon \, \psi^{(1)} + \varepsilon^2 \psi^{(2)} + \cdots . \tag{2.6}$$

Our aim in this section is to compute the leading-order flow $\psi^{(0)}$, given its initial value and the boundary deformation $b(\varepsilon t)$, and to show that it depends only on the boundary shape Λ and not on its time history.

First we note that the boundary conditions (2.4) imply that on ∂D_Λ,

$$\psi^{(1)} = b \qquad \text{and} \qquad \psi^{(n)} = 0 \text{ for } n = 0, 2, 3, \cdots . \tag{2.7}$$

Since the total vorticity ω is advected by the flow, the boundary ∂D_Λ is a vorticity contour and thus we can take $\omega = \omega^{(0)}$ and $\omega^{(n)} = 0$ for $n = 1, 2, \cdots$ there.

Substituting (2.6) into (2.1), we find

$$[\psi^{(0)}, \omega^{(0)}] + \partial_t \omega^{(0)} + \varepsilon \, [\psi^{(1)}, \omega^{(0)}] + \varepsilon \, [\psi^{(0)}, \omega^{(1)}] + \varepsilon \, \partial_t \omega^{(1)} + O(\varepsilon^2) = 0. \tag{2.8}$$

If the fluid flow is stable in the absence of boundary deformation, we expect that the flow will evolve only slowly when the boundary is deforming. We therefore introduce the slow time

$$\tau = \varepsilon t, \tag{2.9}$$

in terms of which (2.8) becomes

$$[\psi^{(0)}, \omega^{(0)}] + \varepsilon \partial_\tau \omega^{(0)} + \varepsilon\, [\psi^{(1)}, \omega^{(0)}] + \varepsilon\, [\psi^{(0)}, \omega^{(1)}] + O(\varepsilon^2) = 0. \tag{2.10}$$

At leading order we obtain

$$[\psi^{(0)}, \omega^{(0)}] = 0. \tag{2.11}$$

Taking into account the fact that $\psi^{(0)} = 0$ on ∂D, we find that the leading-order flow $\psi^{(0)}$ is *instantaneously steady*. The relation (2.11) implies that there exists a scalar function G relating $\omega^{(0)}$ and $\psi^{(0)}$,

$$\psi^{(0)} = G(\omega^{(0)}; \tau). \tag{2.12}$$

As noted, the function G depends on the slow time τ, regarded here as a parameter for reasons which will be apparent later. We define F as the inverse of G: $G(F(u;\tau);\tau) = u$ for every u and τ. With an abuse of notation, we will often write G' for $G' \circ \omega^{(0)} = \boldsymbol{\nabla}\psi^{(0)}/\boldsymbol{\nabla}\omega^{(0)}$ and F' for $F' \circ \psi^{(0)} = \boldsymbol{\nabla}\omega^{(0)}/\boldsymbol{\nabla}\psi^{(0)}$; what is meant will be clear from the context.

At $O(\varepsilon)$ we have

$$\partial_\tau \omega^{(0)} + [\psi^{(1)}, \omega^{(0)}] + [\psi^{(0)}, \omega^{(1)}] = 0. \tag{2.13}$$

Using (2.12), the second term can be written as

$$[\psi^{(0)}, \omega^{(1)}] = G'[\omega^{(0)}, \Delta\psi^{(1)}] = [\omega^{(0)}, G'\Delta\psi^{(1)}], \tag{2.14}$$

with which (2.13) becomes

$$\partial_\tau \omega^{(0)} + [\phi, \omega^{(0)}] = 0, \tag{2.15}$$

$$\phi = [1 - G'\Delta]\, \psi^{(1)}. \tag{2.16}$$

These two equations imply that the leading-order vorticity $\omega^{(0)}$ is *rearranged* by a divergence-free velocity field $\boldsymbol{\nabla}^\perp \phi$ with ϕ related to the first-order streamfunction $\psi^{(1)}$ by (2.16).

2.2 Determination of the Eulerian flow

We now show how the leading order flow $\psi^{(0)}$ can be determined from (2.12) and the fact that $\omega^{(0)}(t)$ is a rearrangement of its initial value $\omega^{(0)}(0)$. We make the following two assumptions on $\psi^{(0)}$:

H1. *The leading-order streamfunction* $\psi^{(0)}$ *is such that it has only one critical point in* D_Λ *(which is necessarily elliptic) and is nonlinearly stable in the sense of Arnold.*

We recall that Arnold stability [cf. Holm et al. (1985)] requires that the steady streamfunction $\psi^{(0)}$ satisfies either (i) $0 < c_1 \leq G' \leq c_2 < \infty$, or (ii) $0 < 1/c_{\mathrm{poi}} < c_1 \leq -G' \leq c_2 < \infty$. In the second condition, c_{poi} is the Poincaré constant for the domain D_Λ, namely the smallest eigenvalue μ of the problem

$$(\Delta + \mu)\, u = 0 \text{ in } D_\Lambda \qquad \text{with} \qquad u = 0 \text{ on } \partial D_\Lambda. \tag{2.17}$$

These conditions ensure that the steady flow is either a minimum or a maximum of the energy for fixed vorticity distribution. Note that H1 implies that

$$-\, c_{\mathrm{poi}} < F' < \infty, \tag{2.18}$$

a condition which will be useful below. The assumption H1 is stronger than that made in WV but it considerably simplifies the solution of (2.40)–(2.42) below.

For the second assumption, we need a little more notation. Let s denote a variable conjugate to $\psi^{(0)}$ in D_Λ, satisfying $[\psi^{(0)}, s] = 1$. Denoting the differential arclength along the curve $\psi^{(0)} = \text{const}$ by $\mathrm{d}l$, we have $\mathrm{d}s = \mathrm{d}l/|\boldsymbol{\nabla}\psi^0|$. We then assume:

H2. *There exists a* $c_\psi > 0$ *such that, for all values of* c *assumed by* $\psi^{(0)}$,

$$\oint_{\psi^{(0)}=c} \mathrm{d}s \leq \frac{1}{c_\psi}. \tag{2.19}$$

In the context adiabatic invariance, this condition is natural: the left-hand side of (2.19) gives the period of rotation of fluid parcels along the streamline $\psi^{(0)} = c$; its boundedness ensures that a time-scale separation between this period and the time scale of the boundary deformation exists for sufficiently small ε. As noted in WV, H2 holds if $\omega_\Lambda \neq 0$ at the fixed point of ψ_Λ.

For concreteness, we henceforth assume that, at $t = 0$, our domain is parameterised by Λ_0 and we choose our coordinates in $\boldsymbol{\mathcal{L}}$ such that $\Lambda_0 = 0$. Furthermore, we fix in $D_{\Lambda_0} \equiv D_0$ a steady leading-order flow $\psi^{(0)}(\boldsymbol{x}, 0) = \psi_0(\boldsymbol{x})$ satisfying H1–H2. Considering only the leading-order flow $\psi^{(0)}(\boldsymbol{x}, t)$ for the moment, we then claim that, assuming H1–H2:

P1. *The flow* $\psi^{(0)}$ *is uniquely determined by (i) the shape of the deformed domain* D_Λ*, (ii) the steadiness condition* (2.12)*, and (iii) the fact that the vorticity* $\omega^{(0)} = \Delta\psi^{(0)}$ *is obtained by rearrangement of the initial vorticity* $\omega_0 = \Delta\psi_0$.

As a result, the leading-order flow at a fixed time t depends only on the shape of the deformed domain at t (parameterized by $\Lambda(\varepsilon t)$), and not on the history of shapes at intermediate times (parameterized by the path $\Lambda(\tau)$, $0 < \tau < \varepsilon t$). One may draw an analogy with adiabatic invariance in finite-dimensional Hamiltonian systems with slowly-varying parameters: here the amplitude is completely determined by the instantaneous value of the parameter, not by its time history.

To emphasize the fact that the leading-order flow depends on Λ instantaneously, we introduce the notation

$$\psi^{(0)} = \psi_\Lambda \quad \text{and} \quad \omega^{(0)} = \omega_\Lambda \tag{2.20}$$

for the leading-order streamfunction and vorticity. We also write $G(\cdot;\tau) =: G_{\Lambda(\tau)}(\cdot)$ and $F(\cdot;\tau) =: F_{\Lambda(\tau)}(\cdot)$. These define the scalar functions G_Λ and F_Λ, both of which have Λ as a parameter. When (and only when) no confusion may arise, we will often write $G_\Lambda \circ \omega_\Lambda$ as G_Λ, $G'_\Lambda \circ \omega_\Lambda$ as G'_Λ, and similarly for F_Λ.

Like the other results in the present paper, the claim P1 is only local: it holds only for sufficiently small domain deformations. A similar result is proved in WV with a precise functional setting and a different (weaker) set of hypotheses. The main idea, which we repeat here for reference, is to reformulate the problem in terms of the area-preserving diffeomorphism

$$g_\Lambda : D_0 \to D_\Lambda : \boldsymbol{x} \mapsto g_\Lambda \boldsymbol{x}, \tag{2.21}$$

which effects the vorticity rearrangement, that is, such that $\omega_\Lambda = \omega_0 \circ g_\Lambda^{-1}$. In terms of the pull-back

$$g_\Lambda^* : \mathcal{C}(D_\Lambda) \to \mathcal{C}(D_0) : f \mapsto f \circ g_\Lambda, \tag{2.22}$$

this can be rewritten as

$$\omega_\Lambda = (g_\Lambda^{-1})^* \omega_0. \tag{2.23}$$

Note that, for fixed ω_0 and ω_Λ, g_Λ is not defined uniquely by (2.23): rearrangements along the lines of constant vorticity clearly have no effect. Correspondingly, the time derivative of g_Λ is not necessarily the divergence-free velocity field $\nabla^\perp\phi$ appearing in (2.15)–(2.16), but the equality

$$\frac{\mathrm{d}}{\mathrm{d}t} g_\Lambda \boldsymbol{x} = \nabla^\perp[\phi(g_\Lambda \boldsymbol{x};\Lambda) + \varpi(\omega_\Lambda(g_\Lambda \boldsymbol{x}))] \tag{2.24}$$

holds, where ϖ is an arbitrary function of one variable. This non-uniqueness, of no importance as far as ψ_Λ and ω_Λ are concerned, will play a crucial role when particle positions are examined in §3.

The map g_Λ satisfies a nonlinear partial differential equation obtained as follows. Since ω_Λ is a steady flow in D_Λ, we have using (2.12),

$$\omega_\Lambda = \Delta(G_\Lambda \circ \omega_\Lambda), \tag{2.25}$$

so applying g_Λ^*, we find

$$\omega_0 = g_\Lambda^* \Delta (g_\Lambda^{-1})^* (G_\Lambda \circ \omega_0). \tag{2.26}$$

The associated boundary conditions are

$$g_\Lambda(\partial D_0) = \partial D_\Lambda \quad \text{and} \quad G_\Lambda = G_0 \tag{2.27}$$

for the boundary value of ω_0, the latter following from the fact that $\psi_\Lambda = \psi_0 = 0$ and $\omega_\Lambda = \omega_0$ on ∂D_Λ.

The partial differential equation (2.26), with g_Λ and G_Λ as unknowns, is shown in WV to have a locally unique solution (modulo translations along vorticity contours) using a contraction mapping argument. This establishes P1 and provides a way of computing g_Λ and G_Λ, and hence ω_Λ and ψ_Λ. Alternatively, P1 can be established using the stability assumption H1: the associated characterisation of steady flows as energy extrema makes it clear that the steady flow ψ_Λ is the (locally unique) extremum in D_Λ with vorticity distribution fixed by ω_0.

We now consider the infinitesimal version of (2.26), that is, we consider the change in g_Λ corresponding to an infinitesimal deformation of the domain. This yields a different construction for g_Λ, based on integration over Λ, and provides all the ingredients needed for the computation of the first-order correction to ψ_Λ and of the Lagrangian flow.

2.3 Infinitesimal deformations

In what follows, we will often make use of the fact that many important quantities are linear in the boundary deformation rate $\dot\Lambda := \mathrm{d}\Lambda/\mathrm{d}\tau$. We will regard these as resulting from the pairing between the vector $\dot\Lambda \in T_\Lambda\mathcal{L}$ and a differential one-form belonging to a dual space. For instance, the function b appearing in the boundary condition (2.4) is linear in $\dot\Lambda$. This makes it possible to define the one-form

$$\boldsymbol{\beta}(\cdot;\Lambda) : T_\Lambda\mathcal{L} \to \mathcal{C}(\partial D_\Lambda) \tag{2.28}$$

by

$$b = \boldsymbol{\beta} \cdot \dot{\Lambda}, \tag{2.29}$$

where $\cdot$ denotes the pairing between vectors and one-forms. Working with differential forms of this type gives a compact notation, factoring out the dependence in $\dot{\Lambda}$. At the same time, it allows for a geometric interpretation of our results as explained in the Discussion.

Let $\mathbf{d}$ be the exterior derivative in $\mathcal{L}$. Since

$$\frac{\mathrm{d}}{\mathrm{d}\tau} g_\Lambda = \mathbf{d} g_\Lambda \cdot \dot{\Lambda}, \tag{2.30}$$

and g_Λ is area preserving, we can define a function-valued one-form Φ by

$$\mathbf{d} g_\Lambda = \boldsymbol{\nabla}^\perp \Phi \circ g_\Lambda. \tag{2.31}$$

An equivalent statement is that

$$\mathbf{d} g_\Lambda^* f = [\Phi, f] \tag{2.32}$$

for any Λ-independent function f. The initial domain $\Lambda_0 = 0$ and initial flow flow ψ_0 having been fixed, Φ depends only on Λ and takes its value in the space of functions in D_Λ; explicitly,

$$\Phi(\cdot;\Lambda) : T_\Lambda \mathcal{L} \to \mathcal{C}(D_\Lambda). \tag{2.33}$$

Alternatively, since $D_\Lambda \subset \mathbb{R}^2$, we can think of Φ as a map from $\mathbb{R}^2$ to the cotangent bundle of $\mathcal{L}$, that is,

$$\Phi : \mathbb{R}^2 \to T^*\mathcal{L}. \tag{2.34}$$

From (2.31), Φ can be recognized as a connection one-form encoding the change in g_Λ that results from an infinitesimal change in Λ (making use of the identification between functions and divergence-free vector fields on D_Λ; see the Discussion for a more precise interpretation). Introducing (formal) coordinates $\{\Lambda_m\}$ in (a neighbourhood of $\Lambda = 0$ in) $\mathcal{L}$, Φ takes the more explicit form $\Phi = \Phi_m \, \mathbf{d}\Lambda_m$, where each Φ_m is a function in D_Λ (sum over repeated indices is implied here and henceforth).

Taking the exterior derivative of (2.23) gives

$$\mathbf{d}\omega_\Lambda + [\Phi, \omega_\Lambda] = 0, \tag{2.35}$$

after using the definition (2.31). In components, this reads

$$\frac{\partial \omega_\Lambda}{\partial \Lambda_m} + [\Phi_m, \omega_\Lambda] = 0. \tag{2.36}$$

Unlike ω_Λ, the leading-order streamfunction ψ_Λ is not simply rearranged as Λ changes. Applying $\mathbf{d}$ to $\psi_\Lambda = G_\Lambda(\omega_\Lambda)$ and using (2.35) show that

$$\mathbf{d}\psi_\Lambda + [\Phi, \psi_\Lambda] = \mathbf{d}G_\Lambda \circ \omega_\Lambda. \tag{2.37}$$

Here and elsewhere, in $\mathbf{d}G_\Lambda \circ \omega_\Lambda$ the exterior derivative is taken with respect to the (parametric) dependence of G_Λ on Λ, so $\mathbf{d}(G_\Lambda \circ \omega_\Lambda) = \mathbf{d}G_\Lambda \circ \omega_\Lambda + (G'_\Lambda \circ \omega_\Lambda)\, \mathbf{d}\omega_\Lambda$.

From (2.35) we derive a property of Φ which will be useful later. Taking $\mathbf{d}$ of (2.35) and using the fact that $\mathbf{d}^2 = 0$, leads, after a short computation detailed in Appendix A, to

$$\mathbf{d}\Phi + \tfrac{1}{2}[\Phi \wedge \Phi] = w \circ \omega_\Lambda \tag{2.38}$$

for some two-form $w \circ \omega_\Lambda : T^2_\Lambda \mathcal{L} \to \mathcal{C}(D_\Lambda)$. Here, the bracket $[\cdot \wedge \cdot]$ is defined in coordinates by

$$[\alpha \wedge \gamma] = [\alpha_m, \gamma_n]\, \mathbf{d}\Lambda_m \wedge \mathbf{d}\Lambda_n \tag{2.39}$$

for any two one-forms $\alpha = \alpha_m\, \mathbf{d}\Lambda_m$ and $\gamma = \gamma_n\, \mathbf{d}\Lambda_n$ with values in $\mathcal{C}(D_\Lambda)$. (Note that in contrast with $[f, f] = 0$ for any function f, $[\alpha \wedge \alpha] \neq 0$ in general.) Equation (2.38) can be interpreted as an integrability condition, an infinitesimal version of the statement that g_Λ is a unique function of Λ modulo displacements along lines of constant ω_Λ.

We next obtain a dynamical equation for Φ. Taking the derivative $\mathbf{d}$ of (2.26) and after a little algebra, we find this equation in the form

$$(\Delta - F'_\Lambda)\, [\Phi, \psi_\Lambda] - \Delta(\mathbf{d}G_\Lambda \circ \omega_\Lambda) = 0. \tag{2.40}$$

The corresponding boundary conditions are

$$\Phi = \boldsymbol{\beta} \qquad \text{on } \partial D_\Lambda, \tag{2.41}$$

which follows from (2.4), (2.29) and (2.16), taking into account that

$$\mathbf{d}G_\Lambda \circ \omega_\Lambda = 0 \qquad \text{on } \partial D_\Lambda, \tag{2.42}$$

which follows from the fact $\psi_\Lambda = 0$ on ∂D_Λ.

Equation (2.40) is the infinitesimal version of (2.26). It can be solved for $[\Phi, \psi_\Lambda]$ and $\mathbf{d}G_\Lambda$ as follows. For any function $u \in \mathcal{C}(D_\Lambda)$, we define the projection $\mathsf{P}_\Lambda u$ by

$$\mathsf{P}_\Lambda\, u := u - \left\{ \oint_{\psi_\Lambda = c} u \;\; \mathrm{d}s \right\} \Big/ \left\{ \oint_{\psi_\Lambda = c} \mathrm{d}s \right\}, \tag{2.43}$$

where, as before, $\mathrm{d}s = \mathrm{d}l / |\boldsymbol{\nabla}\psi_\Lambda|$. It follows from this definition that if u is constant on a contour of constant ψ_Λ, $\mathsf{P}_\Lambda u = 0$. Note that since the contours of ω_Λ and ψ_Λ coincide, a equivalent definition of P_Λ could have been given in terms of integrals along vorticity contours $\omega_\Lambda = c$. The regularity of P_Λ is guaranteed by H2. Letting $\varphi = [\psi_\Lambda, \Phi] - \mathbf{d}G_\Lambda \circ \omega_\Lambda$, and using the facts that $\mathsf{P}_\Lambda[\psi_\Lambda, \Phi] = [\psi_\Lambda, \Phi]$ and $\mathsf{P}_\Lambda(\mathbf{d}G_\Lambda \circ \omega_\Lambda) = 0$, we then have

$$[\psi_\Lambda, \Phi] = \mathsf{P}_\Lambda\, \varphi \quad \text{and} \quad \mathbf{d}G_\Lambda \circ \omega_\Lambda = (1 - \mathsf{P}_\Lambda)\, \varphi. \tag{2.44}$$

Hence we can write (2.40) as

$$(\Delta - F_\Lambda'\, \mathsf{P}_\Lambda)\, \varphi = 0, \tag{2.45}$$

which is a linear pseudodifferential equation involving φ only. Following (2.41) and (2.42), the boundary conditions for φ are

$$\varphi = [\psi_\Lambda, \boldsymbol{\beta}] \qquad \text{on } \partial D_\Lambda. \tag{2.46}$$

It is shown in Appendix B that (2.45)–(2.46) can be solved uniquely for φ. Using (2.44), we recover $[\psi_\Lambda, \Phi]$ and $\mathbf{d}G_\Lambda$. From $[\psi_\Lambda, \Phi]$, Φ can be inferred up to an arbitrary function-valued one-form depending on $\boldsymbol{x}$ through ψ_Λ or, equivalently, through ω_Λ. Thus, there is an equivalence class of forms Φ satisfying (2.40) which is associated with the gauge transformation

$$\Phi \mapsto \Phi + \Pi \circ \omega_\Lambda, \tag{2.47}$$

where $\Pi \circ \omega_\Lambda$ is any function-valued one-form depending on $\boldsymbol{x}$ through ω_Λ. This non-uniqueness simply reflects at the infinitesimal level the non-uniqueness of g_Λ. A particular, uniquely-defined representative of the equivalence class of Φ could be taken to be $\mathsf{P}_\Lambda \Phi$, that is, the one with vanishing average along streamlines $\psi_\Lambda = \text{const}$. This is an arbitrary choice, however, and we will see in the next section that another choice imposes itself naturally.

As shown in WV, once we solve the linear problem (2.40), the solution of the nonlinear problem (2.26) for g_Λ follows, at least in a neighbourhood of $\Lambda = 0$ and subject to sufficient smoothness of the flow and the domain. For a fixed sequence of boundary deformation, that is, for a fixed path $\Lambda(\tau) \subset \boldsymbol{\mathcal{L}}$, one can in principle solve (2.40) and find Φ for each Λ as long as the flows ψ_Λ encountered along the path satisfy H1–H2. Note that (2.40) is consistent with the integrability condition (2.38) which thus remains satisfied along the path (see Appendix A). This confirms our main conclusion, namely that g_Λ is independent of the path, up to translation along contours of ω_Λ.

3 Eulerian Flow: First-order Correction

We now turn to the derivation of the first correction $\psi^{(1)}$ to the leading-order flow ψ_Λ. This derivation is necessary, in particular, to determine the trajectories of fluid particles over the $O(\varepsilon^{-1})$ time scales of interest. Remarkably, $\psi^{(1)}$

can be derived from the knowledge of Φ alone. In the process, the gauge of Φ is fixed in what we argue is a natural manner.

The derivation starts by noting that (2.24) and (2.31) imply that ϕ and $\Phi \cdot \dot{\Lambda}$ differ by a function of ω_Λ only. Thus we can write

$$\phi = \Phi^\star \cdot \dot{\Lambda}, \tag{3.1}$$

where

$$\Phi^\star = \mathsf{P}_\Lambda \Phi + \Pi^\star \circ \omega_\Lambda. \tag{3.2}$$

Here $\Phi^\star$ is a specific member of the class of equivalent one-forms Φ: it corresponds to the unique choice of the gauge $\Pi = \Pi^\star$ in (2.47) that ensures that (3.1) holds. In this sense $\Phi^\star$ can be seen as a natural choice of connection form. The computation which follows shows how it can be obtained from $\mathsf{P}_\Lambda \Phi$.

Since $\psi^{(1)}$, like ϕ, is linear in $\dot{\Lambda}$, we can write

$$\psi^{(1)} = \Psi^{(1)} \cdot \dot{\Lambda}, \tag{3.3}$$

where, $\Psi^{(1)}$, like Φ, is a function-valued form; their relationship follows from (2.16) as

$$(1 - G'_\Lambda \Delta)\Psi^{(1)} = \mathsf{P}_\Lambda \Phi + \Pi^\star \circ \omega_\Lambda. \tag{3.4}$$

Both $\Psi^{(1)}$ and $\Pi^\star$ can be deduced from (3.4). To show this, we make use of the constraint imposed by the material conservation of the total vorticity ω. This implies that the function

$$\mathcal{A}(\Omega; \omega) := \int_{\mathrm{int}\{\omega = \Omega\}} \mathrm{d}^2\boldsymbol{x} = \text{area bounded by } \{\omega = \Omega\}, \tag{3.5}$$

where $\mathrm{int}\{\omega = \Omega\}$ denotes the interior of the curve $\omega = \Omega$, is an exact invariant of the dynamics. Since both the total and leading-order vorticities ω and ω_Λ are rearrangements of the initial vorticity ω_0,

$$\mathcal{A}(\Omega; \omega) = \mathcal{A}(\Omega; \omega_\Lambda) = \mathcal{A}(\Omega; \omega_0). \tag{3.6}$$

Expanding $\omega = \omega_\Lambda + \varepsilon \omega^{(1)} + \cdots$, we then have

$$\mathcal{A}(\Omega; \omega_\Lambda + \varepsilon \omega^{(1)}) - \mathcal{A}(\Omega; \omega_\Lambda) = O(\varepsilon^2), \tag{3.7}$$

or, after some manipulations,

$$\oint_{\omega_\Lambda = \Omega} \omega^{(1)} \, \mathrm{d}s = 0. \tag{3.8}$$

The last equation, which can be rephrased as $(1 - \mathsf{P}_\Lambda)\, \omega^{(1)} = 0$ or

$$(1 - \mathsf{P}_\Lambda)\Delta\Psi^{(1)} = 0, \tag{3.9}$$

provides the solvability condition for (3.4). Indeed, applying $(1-\mathsf{P}_\Lambda)$ to (3.4) gives

$$\Pi^\star \circ \omega_\Lambda = (1-\mathsf{P}_\Lambda)\Psi^{(1)}. \tag{3.10}$$

This reduces (3.4) to

$$(\Delta - F_\Lambda' \mathsf{P}_\Lambda)\Psi^{(1)} = -F_\Lambda' \mathsf{P}_\Lambda \Phi. \tag{3.11}$$

The associated boundary condition follows from (2.7) as

$$\Psi^{(1)} = \boldsymbol{\beta} \quad \text{on } \ \partial D_\Lambda. \tag{3.12}$$

Equation (3.11) is well posed, with a right-hand side that is uniquely defined in spite of the gauge freedom in Φ. The operator on the left-hand side is the same as that in (2.45) and hence its invertibility can be established using the same arguments, detailed in Appendix B. Once $\Psi^{(1)}$ is determined from (3.11), $\Pi^\star$ follows from (3.10), and the natural connection $\Phi^\star$ is obtained. Note that (3.2) and (3.10) imply that it satisfies

$$(1-\mathsf{P}_\Lambda)\Psi^{(1)} = (1-\mathsf{P}_\Lambda)\Phi^\star \qquad \Leftrightarrow \qquad \oint_{\psi_\Lambda = c} \Psi^{(1)}\, \mathrm{d}s = \oint_{\psi_\Lambda = c} \Phi^\star \, \mathrm{d}s. \tag{3.13}$$

This relation turns out to be crucial for the computation of fluid particle trajectories in the next section.

4 Lagrangian Flow: Geometric Angle

In this section we study the evolution of fluid (or tracer) particles in our flow over a timescale $\tau = O(1)$.

4.1 Hamiltonian Formulation

Up to this point, our description of the Eulerian dynamics has been (mostly) coordinate-independent. But in order to study particle positions, we need to introduce explicit coordinates (x, y) in D_Λ; (x, y) is chosen to coincide with the fixed coordinates in the ambient space $\mathbb{R}^2$ through which $D_{\Lambda(\varepsilon t)}$ moves.

The evolution of a particle with position $(x(t), y(t))$ moving with the fluid is governed by the Hamiltonian system

$$\frac{\mathrm{d}x}{\mathrm{d}t} = -\frac{\partial \psi}{\partial y} \quad \text{and} \quad \frac{\mathrm{d}y}{\mathrm{d}t} = \frac{\partial \psi}{\partial x}, \tag{4.1}$$

with the streamfunction ψ acting as the Hamiltonian. Our aim here is to obtain an estimate of $(x(t), y(t))$ with an error of $O(\varepsilon)$ for $\tau = O(1)$, so in the rest of this section we put

$$H(x, y, t) = \psi_{\Lambda(\varepsilon t)}(x, y) + \varepsilon \Psi^{(1)}(x, y; \Lambda(\varepsilon t)) \cdot \dot{\Lambda} \tag{4.2}$$

in place of ψ in (4.1), keeping in mind the validity of this approximation.

For $\varepsilon = 0$ and hence Λ constant, the Hamiltonian (4.2) is integrable. For $\varepsilon \neq 0$, two types of perturbations make it non-integrable: the slow time dependence of ψ_Λ introduced by the time dependence of Λ, and the $O(\varepsilon)$ change introduced by the addition of $\psi^{(1)} = \Psi^{(1)} \cdot \dot{\Lambda}$. We examine the combined effect of these two perturbations following closely the approach of Berry (1985).

Since the leading-order Hamiltonian ψ_Λ is integrable for fixed Λ, we first change to action–angle variables [cf. (Arnold, 1989, pp. 297ff)]. At each (x, y), we define the action I by

$$I(x, y) = \frac{1}{2\pi} \int_{\mathrm{int}\{\psi_\Lambda = \psi_\Lambda(x,y)\}} \mathrm{d}x\,\mathrm{d}y =: \frac{1}{2\pi} A(\psi_\Lambda). \tag{4.3}$$

The angle θ is defined as the variable conjugate to I, $[I, \theta] = 1$. It is 2π-periodic since the contours of ψ_Λ are closed and it is related to the variable s used earlier by

$$2\pi\,\mathrm{d}s = A'(\psi_\Lambda)\,\mathrm{d}\theta. \tag{4.4}$$

The canonical transformation $(x, y) \mapsto (I, \theta)$ is obtained by a generating function $S(I, y; \Lambda)$, with

$$x = \frac{\partial S}{\partial y} \quad \text{and} \quad \theta = \frac{\partial S}{\partial I}. \tag{4.5}$$

Solving these implicit equations, we can write

$$x = X(I, \theta; \Lambda) \quad \text{and} \quad y = Y(I, \theta; \Lambda). \tag{4.6}$$

With these and (4.3), we define

$$\begin{aligned} \hat{\psi}_\Lambda(I; \Lambda) &= \psi^{(0)}(X(I, \theta; \Lambda), Y(I, \theta; \Lambda); \Lambda) = A^{-1}(2\pi I; \Lambda), \\ \hat{\Psi}^{(1)}(I, \theta; \Lambda) &= \Psi^{(1)}(X(I, \theta; \Lambda), Y(I, \theta; \Lambda); \Lambda). \end{aligned} \tag{4.7}$$

Here and in the rest of this section, we denote by a hât quantities considered as functions of (I, θ).

So far we considered a fixed value of Λ. Now let Λ evolve slowly in time, $\Lambda = \Lambda(\varepsilon t)$. The equations of motion in (I, θ) variables are

$$\frac{\mathrm{d}I}{\mathrm{d}t} = -\frac{\partial \hat{H}}{\partial \theta} \quad \text{and} \quad \frac{\mathrm{d}\theta}{\mathrm{d}t} = \frac{\partial \hat{H}}{\partial I}, \tag{4.8}$$

where the new Hamiltonian $\hat{H}(I,\theta;\Lambda)$ is related to $H(x,y;\Lambda)$ by

$$\hat{H}(I,\theta;\Lambda) = H(X(I,\theta;\Lambda), Y(I,\theta;\Lambda);\Lambda) + \frac{\partial S}{\partial t}. \tag{4.9}$$

We note an abuse of notation here: properly speaking $H = H(x,y,t)$, but since the t-dependence only enters through $\Lambda(\varepsilon t)$ and its derivative, we have written $H = H(x,y;\Lambda(\varepsilon t))$. Differentiating the definition

$$\hat{S}(I,\theta;\Lambda) = S(I, Y(I,\theta;\Lambda);\Lambda) \tag{4.10}$$

with respect to t at fixed (I,θ) gives

$$\mathbf{d}\hat{S}\cdot\frac{\mathrm{d}\Lambda}{\mathrm{d}t} = \frac{\partial S}{\partial t} + \frac{\partial S}{\partial y}\frac{\partial Y}{\partial t} = \frac{\partial S}{\partial t} + X\mathbf{d}Y\cdot\frac{\mathrm{d}\Lambda}{\mathrm{d}t} \tag{4.11}$$

Upon substituting $\partial S/\partial t$ into (4.9), we obtain that

$$\begin{aligned}\hat{H}(I,\theta;\Lambda) = \hat{\psi}_\Lambda(I) &+ \varepsilon\hat{\Psi}^{(1)}(I,\theta;\Lambda)\cdot\dot{\Lambda} \\ &+ \varepsilon\Big\{\mathbf{d}\hat{S}(I,\theta;\Lambda) - X(I,\theta;\Lambda)\mathbf{d}Y(I,\theta;\Lambda)\Big\}\cdot\dot{\Lambda}.\end{aligned} \tag{4.12}$$

Since particles are attached to contours of vorticity $\omega = \text{const}$, which only deviate by $O(\varepsilon)$ from the corresponding contours of ω_Λ, the action can only vary by $O(\varepsilon)$ over timescales $\tau \sim O(1)$. This is also evident from direct computation: since $\hat{H}$ is independent of θ at leading order and is periodic in θ at the next order,

$$\frac{\mathrm{d}I}{\mathrm{d}t} = -\varepsilon\frac{\partial}{\partial\theta}\Big\{\hat{\Psi}^{(1)} + \mathbf{d}\hat{S} - X\mathbf{d}Y\Big\}\cdot\dot{\Lambda}, \tag{4.13}$$

and the principle of averaging [cf. (Arnold, 1989, § 52)] implies that I changes only by $O(\varepsilon)$ for $\tau = O(1)$.

The behaviour of the angle variable is more interesting. From (4.8) we have

$$\frac{\mathrm{d}\theta}{\mathrm{d}t} = \frac{\partial\hat{\psi}_\Lambda}{\partial I} + \varepsilon\frac{\partial}{\partial I}\Big\{\hat{\Psi}^{(1)} + \mathbf{d}\hat{S} - X\mathbf{d}Y\Big\}\cdot\dot{\Lambda}. \tag{4.14}$$

The change in the angle $\Delta\theta := \theta(\tau) - \theta(0)$ can then be expressed as $\Delta\theta = \Delta\theta_{\mathrm{dyn}} + \Delta\theta_{\mathrm{geo}}$. The dynamic phase $\Delta\theta_{\mathrm{dyn}}$ simply arises from the instantaneous frequency of the particle, which is the first term in (4.14) above,

$$\Delta\theta_{\mathrm{dyn}} = \frac{1}{\varepsilon}\frac{\partial}{\partial I}\int_0^\tau \hat{\psi}_{\Lambda(\tau')}(I)\,\mathrm{d}\tau'. \tag{4.15}$$

The other terms make up the geometric angle $\Delta\theta_{\mathrm{geo}}$.

4.2 Geometric angle $\Delta\theta_{\text{geo}}$

In this subsection we show that, as in the finite-dimensional cases of Hannay (1985) and Berry (1985), the angle $\Delta\theta_{\text{geo}}$ can be understood in geometric terms as the (an)holonomy of a connection as a closed path is traversed in a parameter space.

From (4.14), the geometric angle $\Delta\theta_{\text{geo}}$ can be written as

$$\begin{aligned}\Delta\theta_{\text{geo}} = \int_0^\tau \frac{\partial}{\partial I}\Big\{\hat{\Psi}^{(1)}(I,\theta;\Lambda(\tau')) + \mathbf{d}S(I,\theta;\Lambda(\tau'))\\ - X(I,\theta;\Lambda(\tau'))\,\mathbf{d}Y(I,\theta;\Lambda(\tau'))\Big\}\cdot\frac{\mathrm{d}\Lambda}{\mathrm{d}\tau'}\,\mathrm{d}\tau'\end{aligned} \tag{4.16}$$

This form suggests that $\Delta\theta_{\text{geo}}$ depends only on the path traversed in $\mathcal{L}$ and not on its time parametrisation. The terms inside the braces do depend on I and θ, but as shown earlier, the total variation of the action I is of $O(\varepsilon)$ over the timescale of interest. The dependence on the periodic variable θ can be removed by averaging. For any function f periodic in θ, let

$$\langle f\rangle := \frac{1}{2\pi}\int_0^{2\pi} f(\theta)\,\mathrm{d}\theta. \tag{4.17}$$

We note that by (4.4) this is essentially equivalent to the projection $1-\mathsf{P}_\Lambda$. Applying $\langle\cdot\rangle$ to (4.16) and replacing $I(t)$ by $I(0)$, we find

$$\Delta\theta_{\text{geo}} = \frac{\partial}{\partial I}\int_{C_\Lambda}\Big\langle\hat{\Psi}^{(1)} + \mathbf{d}S - X\,\mathbf{d}Y\Big\rangle + O(\varepsilon), \tag{4.18}$$

where C_Λ is the path traversed in $\mathcal{L}$ and where the integrand depends only on I and Λ.

Because of the arbitrariness in the angle coordinates (depending on our choice of $\theta = 0$ for each Λ), the geometric angle is only unambiguously defined when the path C_Λ is closed, that is, when $\Lambda(\tau) = \Lambda(0) = 0$. Following Hannay (1985) and Berry (1985), we consider this scenario, which is illustrated in Figure 2. Since $\mathbf{d}S$ is exact, it vanishes when integrated around C_Λ. Using Stokes' theorem in $\mathcal{L}$, the remaining terms in (4.18) can be written as

$$\Delta\theta_{\text{geo}} = \frac{\partial}{\partial I}\int_{\mathcal{S}_\Lambda}\Big\langle\mathbf{d}\hat{\Psi}^{(1)} - \mathbf{d}X\wedge\mathbf{d}Y\Big\rangle \tag{4.19}$$

where $\mathcal{S}_\Lambda$ is a two-dimensional surface bounded by C_Λ. The second term is identical to that obtained by Berry (1985; eq. (18)) for general Hamiltonian systems depending slowly on time; the first term results from the $O(\varepsilon)$ change to the Hamiltonian induced by the boundary deformation.

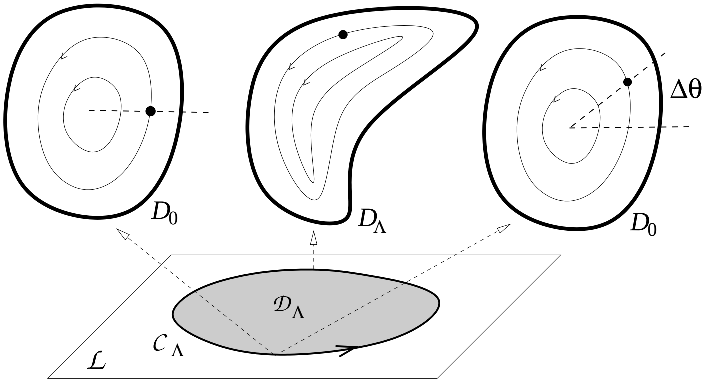

Fig. 2. Angle change for a cyclic domain deformation. As $\Lambda(\tau)$ describes the closed loop $\mathcal{C}_\Lambda \subset \mathcal{L}$, with interior $\mathcal{D}_\Lambda$, the fluid domain D_Λ is deformed and returns to its original shape. Fluid particles remain on vorticity contours which approximately coincide with streamlines. The position of the particles along vorticity contours is defined by the angle-like variable θ whose total change $\Delta\theta$ includes the geometric contribution $\Delta\theta_{\text{geo}}$ which depends only on the geometrical properties of $\mathcal{D}_\Lambda$.

Now $\langle\hat{\Psi}^{(1)}\rangle = \langle\hat{\Phi}^\star\rangle$ by (3.13), so the first term in the integral can be written as

$$\langle\mathbf{d}\hat{\Psi}^{(1)}\rangle = \langle\mathbf{d}\hat{\Phi}^\star\rangle. \tag{4.20}$$

As for the second term, we use the fact that g_Λ is a canonical transformation (since it is area-preserving) to write

$$\boldsymbol{X}(I,\theta;\Lambda) = g_\Lambda \boldsymbol{X}(I,\theta;0), \tag{4.21}$$

thus defining the transformation to action–angle coordinates for all values of Λ in terms of the transformation at $\Lambda = 0$.

It follows from this and (2.31) that

$$\mathbf{d}\boldsymbol{X}(I,\theta;\Lambda) = \boldsymbol{\nabla}^\perp\Phi\Big|_{\boldsymbol{X}(I,\theta;\Lambda)}. \tag{4.22}$$

We then have

$$\begin{aligned}\mathbf{d}X\wedge\mathbf{d}Y = \frac{\partial X}{\partial\Lambda_m}\frac{\partial Y}{\partial\Lambda_n}\,\mathbf{d}\Lambda_m\wedge\mathbf{d}\Lambda_n \quad &= -\frac{\partial\Phi_m}{\partial Y}\frac{\partial\Phi_n}{\partial X}\,\mathbf{d}\Lambda_m\wedge\mathbf{d}\Lambda_n \\ = \tfrac{1}{2}[\Phi_m,\Phi_n]\,\mathbf{d}\Lambda_m\wedge\mathbf{d}\Lambda_n \quad &= \tfrac{1}{2}[\Phi\wedge\Phi] = \tfrac{1}{2}[\Phi^\star\wedge\Phi^\star],\end{aligned} \tag{4.23}$$

where the last equality follows from the fact that the bracket is independent of the gauge choice for Φ. Furthermore, the fact that the transformation to action–angle variables is canonical implies that

$$\tfrac{1}{2}[\Phi^\star\wedge\Phi^\star] = \tfrac{1}{2}[\hat{\Phi}^\star\wedge\hat{\Phi}^\star], \tag{4.24}$$

where the second bracket is in terms of (I,θ). We can therefore write (4.19) as

$$\Delta\theta_{\text{geo}} = \frac{\mathrm{d}}{\mathrm{d}I}\int_{\mathcal{S}_\Lambda}\Big\langle\mathbf{d}\hat{\Phi}^\star - \tfrac{1}{2}[\hat{\Phi}^\star\wedge\hat{\Phi}^\star]\Big\rangle. \tag{4.25}$$

A last step, detailed in Appendix A, shows that

$$\kappa := \mathbf{d}\hat{\Phi}^\star - \tfrac{1}{2}[\hat{\Phi}^\star \wedge \hat{\Phi}^\star] = \mathbf{d}\Phi^\star + \tfrac{1}{2}[\Phi^\star \wedge \Phi^\star]. \tag{4.26}$$

This function-valued two-form can be recognised as the curvature of the connection $\Phi^\star$, and according to (2.38), it depends on space through ω_Λ or, equivalently, through I only. This property stems from the constraints of area and vorticity preservation imposed on the particle motion along vorticity contours. The average in (4.25) is therefore superfluous, and we obtain the result:

P2. *The geometric angle of a particle caused by the slow deformation of the boundary is given by*

$$\Delta\theta_{\mathrm{geo}} = \frac{\mathrm{d}}{\mathrm{d}I}\int_{\mathcal{S}_\Lambda} \kappa, \tag{4.27}$$

where κ, given in (4.26), *is the curvature of $\Phi^\star$ and depends only on the action I of the particle and on the domain shape parameterised by Λ.*

5 Small boundary deformation

As a concrete illustration of the developments so far, we consider the case where the total boundary deformation is small. In general, computing g_Λ in (2.21) requires either solving (2.26) or integrating the differential equation (2.15) with boundary condition $\phi = b$ [cf. (2.41)], which would have to be done numerically. Analytic progress is possible, however, if one considers boundary deformations that are sufficiently small for a perturbative approach to be applicable. In this section we develop such an approach systematically using Lie series [cf. Lichtenberg and Lieberman (1992)].

Let δ be a formal small parameter characterising the smallness of the boundary deformation. The function $B(\boldsymbol{x};\Lambda)$ defining D_Λ can then be expanded as

$$B(\boldsymbol{x};\Lambda) = B_0(\boldsymbol{x}) + \delta B_1(\boldsymbol{x};\Lambda) + \delta^2 B_2(\boldsymbol{x};\Lambda) + \cdots, \tag{5.1}$$

where B_0 is independent of Λ (recall that $\Lambda_0 = 0$), B_1 is linear in Λ, B_2 quadratic, etc. Since g_Λ is close to the identity and area-preserving, it may be regarded as the flow at 'time' δ of an associated δ-dependent divergence-free vector field given by $\nabla^\perp\rho$ for some function $\rho(\boldsymbol{x},\delta)$. (Here ρ is to be considered to live in $\mathcal{C}(ND \times I)$, where $ND \subset \mathbb{R}^2$ is large enough to contain all relevant D_Λ and $I \subset \mathbb{R}$.) Correspondingly, the pull-back of g_Λ defined in (2.22) satisfies

$$\frac{\mathrm{d}g_\Lambda^*}{\mathrm{d}\delta} = g_\Lambda^*[\rho, \cdot]. \tag{5.2}$$

Expanding ρ in powers of δ as

$$\rho = \rho_1 + \delta\rho_2 + \cdots \tag{5.3}$$

and introducing into (5.2) lead to the expansions

$$g_\Lambda^* = 1 + \delta[\rho_1, \cdot] + \frac{\delta^2}{2}\Big([\rho_2, \cdot] + [\rho_1, [\rho_1, \cdot]]\Big) + \cdots , \tag{5.4}$$

$$(g_\Lambda^{-1})^* = 1 - \delta[\rho_1, \cdot] - \frac{\delta^2}{2}\Big([\rho_2, \cdot] - [\rho_1, [\rho_1, \cdot]]\Big) + \cdots . \tag{5.5}$$

Computing $g_\Lambda^* f$ for an arbitrary Λ-independent f using (5.4), taking the exterior derivative and identifying with (2.32) lead to

$$\Phi = \delta \mathbf{d}\rho_1 + \frac{\delta^2}{2}\Big(\mathbf{d}\rho_2 + [\mathbf{d}\rho_1, \rho_1]\Big) + \cdots , \tag{5.6}$$

up to an arbitrary function of ω_Λ, after using the Jacobi identity.

Introducing (5.4)–(5.5) into (2.26) leads to a sequence of partial differential equations for the coefficients of ρ. The first two read

$$(\Delta - F_0')[\rho_1, \psi_0] - \Delta\chi_1 = 0, \tag{5.7}$$

$$\begin{aligned}(\Delta - F_0')[\rho_2, \psi_0] - 2\Delta\chi_2 = &-2[\rho_1, \Delta[\rho_1, \psi_0]] + [\rho_1, [\rho_1, \omega_0]] \\ &+ \Delta[\rho_1, [\rho_1, \psi_0]] + 2[\rho_1, \Delta\chi_1] - 2\Delta[\rho_1, \chi_1],\end{aligned} \tag{5.8}$$

where F_0' is shorthand for $F_0' \circ \psi_0$, and we have introduced the expansion

$$G_\Lambda \circ \omega_0 = \psi_0 + \delta\chi_1 + \delta^2\chi_2 , \cdots , \tag{5.9}$$

with χ_i, $i = 1, 2 \cdots$, depending on $\boldsymbol{x}$ through $\omega_0(\boldsymbol{x})$. These equations are supplemented by the boundary conditions

$$[\rho_1, B_0] = -B_1, \tag{5.10}$$

$$[\rho_2, B_0] = -2B_2 - 2[\rho_1, B_1] - [\rho_1, [\rho_1, B_0]], \tag{5.11}$$

to be applied on the curve $B_0(\boldsymbol{x}) = B(\boldsymbol{x}; 0) = 0$. The formulation is then relatively simple, with all the equations to be solved in the original domain D_0. The functions χ_n, $n = 1, 2, \cdots$ are found from solvability conditions. These can be made explicit using the same method as in the treatment of (2.40). For instance, using the projection operator P_0 associated with lines of constant ψ_0, (5.7) can be rewritten as

$$(\Delta - F_0'\mathsf{P}_0)\,\varphi = 0 \tag{5.12}$$

where $\varphi := [\rho_1, \psi_0] - \chi_1$, implying that

$$[\rho_1, \psi_0] = \mathsf{P}_0\varphi \quad \text{and} \quad \chi_1 = (1 - \mathsf{P}_0)\varphi. \tag{5.13}$$

Once the ρ_n, $n = 1, 2, \cdots$, are computed, the leading-order vorticity and streamfunction follow readily from

$$\omega_\Lambda = \omega_0 - \delta[\rho_1, \omega_0] - \frac{\delta^2}{2}\Big([\rho_2, \omega_0] - [\rho_1, [\rho_1, \omega_0]]\Big) + \cdots , \tag{5.14}$$

$$\begin{aligned} \psi_\Lambda = \psi_0 &- \delta\Big([\rho_1, \psi_0] - \chi_1\Big) \\ &- \frac{\delta^2}{2}\Big([\rho_2, \psi_0] - [\rho_1, [\rho_1, \psi_0]] - 2\chi_2\Big) + \cdots . \end{aligned} \tag{5.15}$$

To find the first-order correction to the Eulerian flow, (3.11) needs to be solved by expansion in powers of δ. This is conveniently done by pulling back this equation to the original domain D_0. To do this, we define the pull-backs (denoted by overbars) and their expansions as

$$\bar\Psi^{(1)} := g_\Lambda^* \Psi^{(1)} = \delta \bar\Psi_1^{(1)} + \delta^2 \bar\Psi_2^{(1)} + \cdots , \tag{5.16}$$

$$\begin{aligned} \bar\Phi := g_\Lambda^* \Phi &= \delta \bar\Phi_1 + \delta^2 \bar\Phi_2 + \cdots \\ &= \delta \mathbf{d}\rho_1 + \frac{\delta^2}{2}\Big(\mathbf{d}\rho_2 - [\mathbf{d}\rho_1, \rho_1]\Big) + \cdots , \end{aligned} \tag{5.17}$$

where the last equality follows from (5.4) and (5.6). Introducing these pull-backs into (3.11) and noting that

$$\begin{aligned} (g_\Lambda^{-1})^* F_\Lambda'(\psi_\Lambda) = (g_\Lambda^{-1})^* [G_\Lambda'(\omega_\Lambda)]^{-1} &= [G_\Lambda'(\omega_0)]^{-1} \\ &= F_0'(\psi_0) - \delta [F_0'(\psi_0)]^2 \frac{\nabla \chi_1}{\nabla \omega_0} + \cdots \end{aligned}$$

leads to

$$(\Delta - F_0' \mathsf{P}_0) \bar\Psi_1^{(1)} = -F_0' \mathsf{P}_0 \bar\Phi_1, \tag{5.18}$$

$$\begin{aligned} (\Delta - F_0' \mathsf{P}_0) \bar\Psi_2^{(1)} &= -F_0' \mathsf{P}_0 \bar\Phi_2 + \Delta[\rho_1, \bar\Psi_1^{(1)}] - [\rho_1, \Delta \bar\Psi_1^{(1)}] \\ &\quad - F_0' \frac{\nabla \chi_1}{\nabla \omega_0} \Delta \bar\Psi_1^{(1)}. \end{aligned} \tag{5.19}$$

These equations, involving the same invertible operator as (5.12), can be solved to find $\bar\Psi^{(1)}$, with $\Psi^{(1)}$ deduced after application of $(g_\Lambda^{-1})^*$. The natural gauge $\Phi^\star$ of Φ then follows from (3.2) and (3.10). Alternatively, one can first compute the pull-back $\bar\Phi^\star$, which is obtained from the relations

$$\bar\Phi^\star = \mathsf{P}_0 \bar\Phi + \Pi^\star \circ \omega_0 \quad \text{and} \quad \Pi^\star \circ \omega_0 = (1 - \mathsf{P}_0) \bar\Psi^{(1)} \tag{5.20}$$

inferred from (3.2) and (3.10), and then deduce $\Phi^\star$ by pushing forward with g_Λ^*.

To compute the curvature κ and the geometric angle, there is in fact no need to push forward $\bar\Psi^{(1)}$ and $\bar\Phi^\star$: indeed, from (4.7) and (4.21), we see that $\hat\Psi^{(1)}$

and $\bar{\Psi}^{(1)}$ are related by the Λ-independent transformation

$$\hat{\Psi}^{(1)}(I,\theta;\Lambda) = \bar{\Psi}^{(1)}(\boldsymbol{X}(I,\theta;0);\Lambda) \tag{5.21}$$

defining the action–angle variables in the original domain D_0. Since $\hat{\Phi}^\star$ and $\bar{\Phi}^\star$ obey an analogous relation, they are essentially equivalent: in particular, $\mathbf{d}\hat{\Phi}^\star = \mathbf{d}\bar{\Phi}^\star$ and $[\hat{\Phi}^\star \wedge \hat{\Phi}^\star] = [\bar{\Phi}^\star \wedge \bar{\Phi}^\star]$. The curvature κ in (4.26) can therefore be computed directly from $\bar{\Phi}^\star$ in a straightforward manner as

$$\kappa = \mathbf{d}\bar{\Phi}^\star - \tfrac{1}{2}[\bar{\Phi}^\star \wedge \bar{\Phi}^\star]. \tag{5.22}$$

Note that, in principle, the first two terms in the expansion of $\bar{\Phi}^\star$ or $\Phi^\star$ need to be computed in order to obtain a leading-order approximation to the geometric angle. This is because $\bar{\Phi}_1^\star$ is independent of Λ, $\mathbf{d}\bar{\Phi}_1^\star = 0$ and hence $\kappa = O(\delta^2)$. The computation can however be shortened by observing that the average of $\bar{\Phi}_2^\star$ along streamlines, that is, $(1-\mathsf{P}_0)\bar{\Phi}_2^\star$, is the only $O(\delta^2)$ quantity genuinely needed if the averaged form (4.25) of κ is used. In turn, $(1-\mathsf{P}_0)\bar{\Phi}_2^\star$ can be approximated by $(1-\mathsf{P}_0)\bar{\Psi}_2^{(1)}$, as the pull-back of (3.11) indicates. The latter quantity satisfies a relatively simple equation, obtained by applying $(1-\mathsf{P}_0)$ to (5.19) to find

$$(1-\mathsf{P}_0)\Delta\bar{\Psi}_2^{(1)} = (1-\mathsf{P}_0)\Big\{\Delta[\rho_1, \bar{\Psi}_1^{(1)}] - [\rho_1, \Delta\bar{\Psi}_1^{(1)}]\Big\}, \tag{5.23}$$

after using $(1-\mathsf{P}_0)\Delta\bar{\Psi}_1^{(1)} = 0$ which follows from (3.9) at leading-order in δ.

6 Nearly axisymmetric flow

We now consider a simple example where the computations of g_Λ and other relevant quantities can be carried out explicitly to $O(\delta^2)$. We assume that for $\Lambda = 0$, the fluid domain is the disc $(r,\sigma) \in [0,1] \times [0,2\pi]$. The deformed domain is defined by

$$r = 1 + \delta \sum_m \Lambda_m \mathrm{e}^{\imath m\sigma} - \frac{\delta^2}{2}\sum_m |\Lambda_m|^2 + O(\delta^3), \tag{6.1}$$

where the $\Lambda_m \in \mathbb{C}$ satisfy $\Lambda_m^* = \Lambda_{-m}$, with * denoting complex conjugate. The multi-dimensional parameter Λ is therefore infinite dimensional: $\Lambda = \{\Lambda_m \in \mathbb{C} : m \in \mathbb{Z}\}$. Area preservation at $O(\delta^2)$ requires that $\Lambda_0 = 0$ and the introduction of the $O(\delta^2)$, σ-independent terms.

The initial flow is taken to be axisymmetric, with vorticity

$$\omega_0(r) = \frac{1}{r}\Big(r\psi_0'(r)\Big)',$$

where the prime denotes differentiation with respect to r. For this flow, (5.7) reduces to

$$\frac{\psi_0'}{r}\Delta\partial_\sigma\rho_1 + 2\Big(\frac{\psi_0'}{r}\Big)'\Big(\partial^2_{r\sigma}\rho_1 - \frac{1}{r}\partial_\sigma\rho_1\Big) + \frac{1}{r}\Big(r\chi_1'\Big)' = 0, \tag{6.2}$$

with χ_1 a function of r only. The corresponding boundary condition is obtained from (5.10) in the form

$$\partial_\sigma\rho_1 = -\sum_m \Lambda_m \mathrm{e}^{\imath m\sigma} \quad \text{at } r = 1. \tag{6.3}$$

The solvability condition for (6.2), found by integration with respect to $\sigma \in [0, 2\pi]$, imposes that $(r\chi_1')' = 0$; boundedness of χ_1 then implies that χ_1 is a constant which we can take equal to zero: $\chi_1 = 0$.

The solution of (6.2) for ρ_1 is then found as the Fourier series

$$\rho_1(r,\sigma) = \sum_m \Lambda_m \rho_{1,m}(r)\,\mathrm{e}^{\imath m\sigma}, \tag{6.4}$$

with $\rho^*_{1,m} = \rho_{1,-m}$. Equation (6.2) does not constrain the $m = 0$ mode $\rho_{1,0}$; this is the result of the gauge freedom for g_Λ. A convenient choice is

$$\rho_{1,0} = 0. \tag{6.5}$$

Introducing (6.4) into (6.2) gives a second-order equation for $\rho_{1,m}$, namely

$$\psi_0'\Big(\rho''_{1,m} - \frac{1}{r}\rho'_{1,m} + \frac{2-m^2}{r^2}\rho_{1,m}\Big) + 2\psi_0''\Big(\rho'_{1,m} - \frac{1}{r}\rho_{1,m}\Big) = 0, \tag{6.6}$$

with associated boundary condition

$$\rho_{1,m} = \frac{\imath}{m} \quad \text{at } r = 1. \tag{6.7}$$

There is a close connection between this equation and the Rayleigh equation for the normal modes of axisymmetric flows (e.g., Drazin and Reid, 1981): (6.6) can be recast as the Rayleigh equation for zero-frequency modes, with $r^{-1}\psi_0'\rho_{1,m}$ as the unknown function. Of course the non-homogeneous boundary condition for $\rho_{1,m}$ differs from the homogeneous boundary condition usually considered for the Rayleigh equation. The connection is useful nevertheless:

the absence of zero-frequency normal modes that can be established from the Rayleigh equation when $\psi_0' \neq 0$ (as guaranteed by the hypothesis H2) implies the existence of a unique solution to (6.6).

We note that the solution for the $m = 1$ mode, which describes a rigid translation of the disc, is independent of ψ_0 and given by $\rho_{1,\pm 1} = \imath \Lambda_{\pm 1} r$. Not surprisingly, this corresponds to a uniform displacement field $\nabla^\perp \rho_1$.

The vanishing of χ_1 indicates that the vorticity–streamfunction relationship is unchanged at leading order in δ. This is a particularity of axisymmetric flows which makes it worthwhile to carry out the calculation to $O(\delta^2)$ so as to demonstrate how a non-zero χ_2 is obtained; this is described in Appendix C.

With ρ_1 determined by its Fourier series (6.4), $\bar{\Phi}_1$ is given by

$$\bar{\Phi}_1 = \sum_m \rho_{1,m}(r) \mathrm{e}^{\imath m \sigma} \mathbf{d}\Lambda_m. \tag{6.8}$$

Because $\rho_{1,0} = 0$ and $1 - \mathsf{P}_0$ is simply the average along circles, (5.18) indicates that $(1 - \mathsf{P}_0)\bar{\Psi}_1^{(1)} = 0$. Equations (5.20) then imply that $\bar{\Phi}_1^\star = \bar{\Phi}_1$. In other words, our choice (6.5) provides the leading-order connection with its natural choice of gauge which corresponds to vanishing average along the circles $r =$ const. Expanding $\bar{\Psi}_1^{(1)}$ in Fourier series as

$$\bar{\Psi}_1^{(1)} = \sum_m \bar{\Psi}_{1,m}^{(1)}(r)\, \mathrm{e}^{\imath m \sigma} \mathbf{d}\Lambda_m, \tag{6.9}$$

(5.18) is reduced to the set of ordinary differential equations

$$\psi_0' \left[\frac{1}{r} \left(r \bar{\Psi}_{1,m}^{(1)}{}' \right)' - \frac{m^2}{r} \bar{\Psi}_{1,m}^{(1)} \right] - \omega_0' \bar{\Psi}_{1,m}^{(1)} = -\omega_0' \rho_{1,m} \tag{6.10}$$

with $\bar{\Psi}_{1,0}^{(1)} = 0$. The associated boundary conditions are found from (3.12) as

$$\bar{\Psi}_{1,m}^{(1)} = \frac{1}{m} \quad \text{at} \quad r = 1. \tag{6.11}$$

Solving (6.10) gives the first-order correction $\Psi_1^{(1)}$ to the Eulerian flow to leading order in δ.

As discussed at the end of §5, the computation of the geometric angle to leading order requires not only $\bar{\Phi}_1^\star$ but also $\bar{\Phi}_2^\star$ or, to minimise computations, $(1 - \mathsf{P}_0)\bar{\Psi}_2^{(1)}$. This is deduced from (5.23) which reduces to the ordinary differential equation

$$\frac{1}{r}\frac{\mathrm{d}}{\mathrm{d}r}\left\{ r \frac{\mathrm{d}}{\mathrm{d}r} (1 - \mathsf{P}_0) \bar{\Psi}_2^{(1)} \right\} = (1 - \mathsf{P}_0) \left\{ \Delta[\rho_1, \bar{\Psi}_1^{(1)}] - [\rho_1, \Delta \bar{\Psi}_1^{(1)}] \right\}. \tag{6.12}$$

Solving this equation leads to an expression for $(1-\mathsf{P}_0)\bar{\Psi}_2^{(1)}$. Taking the differential yields the first term of the curvature κ in (5.22) as

$$\langle \mathbf{d}\bar{\Phi}^{\star}\rangle = (1-\mathsf{P}_0)\mathbf{d}\bar{\Psi}_2^{(1)} + O(\delta^3). \tag{6.13}$$

Note that since ρ_1 is linear in Λ_m and $\bar{\Psi}_1^{(1)}$ is Λ-independent, $(1-\mathsf{P}_0)\bar{\Psi}_2^{(1)}$ is linear in Λ_m; furthermore, because the averaging $1-\mathsf{P}_0$ along circles eliminates all products in the right-hand side of (6.12) except for those of complex-conjugate Fourier modes, $(1-\mathsf{P}_0)\bar{\Psi}_2^{(1)}$ is a linear combination of terms of the type $\Lambda_m \mathbf{d}\Lambda_m^*$. Therefore, $\langle \mathbf{d}\bar{\Phi}^{\star}\rangle$ is given by a Λ-independent linear combination of the two-forms $\mathbf{d}\Lambda_m \wedge \mathbf{d}\Lambda_m^*$.

The second term in (5.22) is also $O(\delta^2)$ and is readily computed from (6.8). Averaging along circles gives it the same form as that of $\langle \mathbf{d}\bar{\Phi}^{\star}\rangle$. This leads to the geometric angle in the form

$$\Delta\theta_{\mathrm{geo}} = \delta^2 \sum_{m>0} f_m(r)\mathcal{A}_m + O(\delta^3), \tag{6.14}$$

for some functions $f_m(r)$. Here we have defined

$$\mathcal{A}_m = -\frac{1}{2}\int_{\mathcal{D}_\Lambda} \mathbf{d}\Lambda_m \wedge \mathbf{d}\Lambda_m^*$$

which be recognised as (minus) the oriented area enclosed by the path described by Λ_m in the complex plane. (A positive $\mathcal{A}_m$ is associated with a rotation of the fluid domain in the positive sense.) Unsurprisingly, at leading order, the geometric angle is the sum of separate contributions of each Fourier mode of the boundary deformation.

6.2 *An example: flow with power-law radial dependence*

As a simple example of an axisymmetric flow, consider the streamfunction

$$\psi_0(r) = Ar^{\alpha} \qquad \text{with } \ 0<\alpha<2, \tag{6.15}$$

for which (6.6)–(6.7) can be solved explicitly, leading to

$$\bar{\Phi}_{1,m} = \rho_{1,m} = \frac{\imath r^{\beta_m}}{m}, \tag{6.16}$$

where

$$\beta_m = \alpha_m - \alpha + 2 \quad \text{and} \quad \alpha_m = \sqrt{m^2+\alpha^2-2\alpha}.$$

The leading-order vorticity in the deformed domain is then found to be

$$\omega_\Lambda(r,\sigma) = \omega_0(r) - \delta\,\omega_0'(r)\sum_m \Lambda_m r^{\beta_m-1}\mathrm{e}^{\imath m\sigma} + O(\delta^2), \tag{6.17}$$

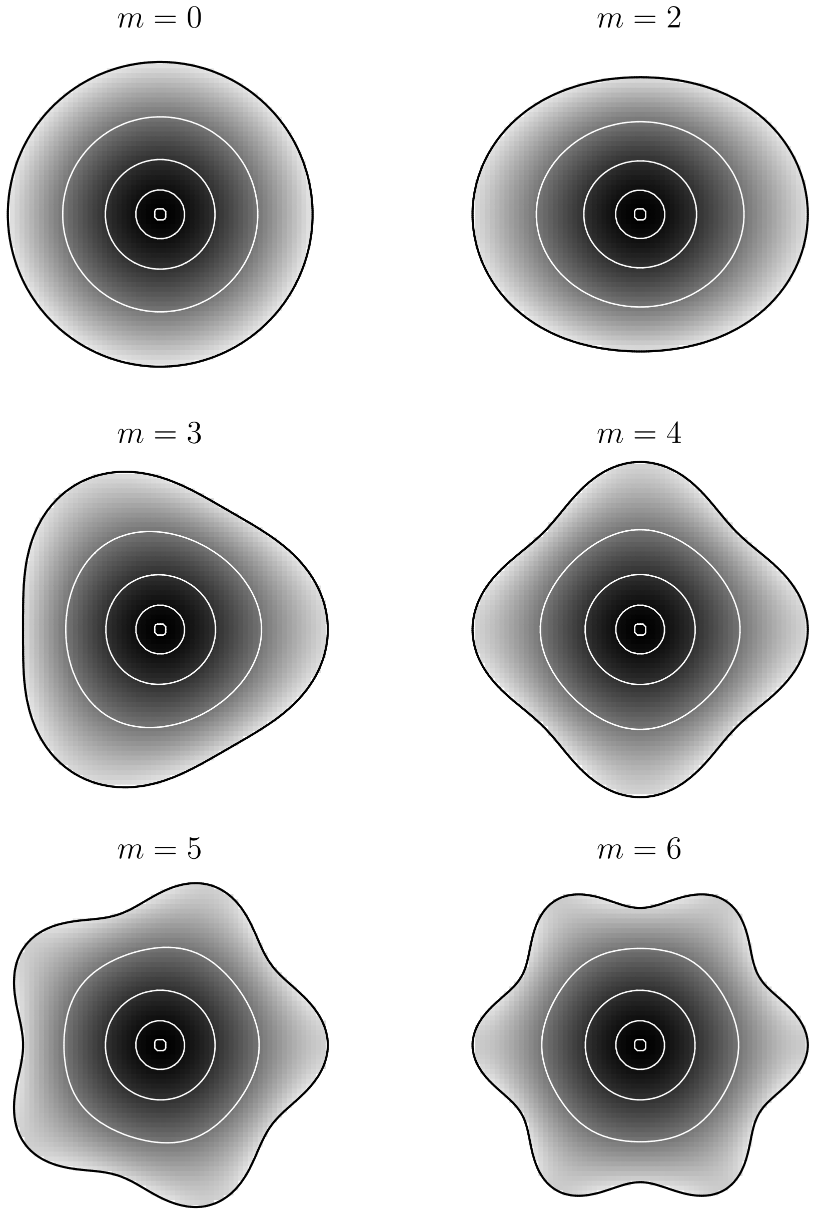

Fig. 3. Vorticity ω_Λ (grey scale) and streamfunction ψ_Λ (white lines) of the leading-order (steady) flow in a slightly deformed disc. The top left panel $m = 0$ shows the undeformed flow, with $\psi_0 = r^{1/2}$; the other panels show the flows obtained when deforming the disc by a single Fourier mode m according to (6.1) with $\delta|\Lambda_m| = 0.05$.

with a similar expression for ψ_Λ. Figure 3 shows these approximations to ω_Λ and ψ_Λ in domains deformed by a single Fourier mode m, with m ranging from 2 to 6, in the case $\alpha = 1/2$.

Equation (6.10) can also be solved explicitly, with the result

$$\bar{\Psi}^{(1)}_{1,m} = \frac{1}{m}\Big[\gamma_m r^{\beta_m} + (1-\gamma_m) r^{\alpha_m}\Big] \qquad \text{where } \gamma_m = \frac{\alpha}{\alpha_m + \beta_m}. \tag{6.18}$$

Introducing into (6.12) gives

$$\begin{aligned}(1-\mathsf{P}_0)\bar{\Psi}_2^{(1)} = -\imath \sum_m \frac{1}{m}\Lambda_m \mathbf{d}\Lambda_m^* \Big[&\gamma_m F(\beta_m,\beta_m) r^{2\beta_m-2} \\ &+ (1-\gamma_m)F(\alpha_m,\beta_m) r^{\alpha_m+\beta_m-2}\Big],\end{aligned} \tag{6.19}$$

where we have defined

$$F(\alpha_m,\beta_m) := \frac{E(\alpha_m,\beta_m)}{\alpha_m+\beta_m-2} := \frac{2\alpha_m\beta_m+\beta_m^2-2\alpha_m-2\beta_m+m^2}{\alpha_m+\beta_m-2}. \tag{6.20}$$

From this and (6.13) we deduce the first component of κ, namely

$$\begin{aligned}\langle \mathbf{d}\bar{\Phi}^\star\rangle = -2\imath\delta^2 \sum_{m>0} \frac{1}{m}\Big[&\gamma_m F(\beta_m,\beta_m) r^{2\beta_m-2} \\ &+ (1-\gamma_m)F(\alpha_m,\beta_m) r^{\alpha_m+\beta_m-2}\Big]\,\mathbf{d}\Lambda_m \wedge \mathbf{d}\Lambda_m^* + O(\delta^3).\end{aligned} \tag{6.21}$$

Using (6.16), the second component of κ is found directly to be

$$\begin{aligned}\langle[\bar{\Phi}^\star \wedge \bar{\Phi}^\star]\rangle &= \frac{\delta^2}{2\pi}\int_0^{2\pi} [\bar{\Phi}_1 \wedge \bar{\Phi}_1]\,\mathrm{d}\sigma + O(\delta^3) \\ &= -4\imath\delta^2 \sum_{m>0} \frac{\beta_m}{m} r^{2\beta_m-2}\,\mathbf{d}\Lambda_m \wedge \mathbf{d}\Lambda_m^* + O(\delta^3).\end{aligned} \tag{6.22}$$

Combining these results with (4.25), and noting that the action–angle variables in the undeformed domain are simply $(I,\theta)=(r^2/2,\sigma)$, leads to the geometric angle in the form (6.14) with

$$f_m(r) = \frac{4}{m}\left(p_m r^{2\beta_m-4} + q_m r^{\alpha_m+\beta_m-4}\right), \tag{6.23}$$

where

$$p_m = \gamma_m E(\beta_m,\beta_m) - 2\beta_m(\beta_m-1) \quad \text{and} \quad q_m = (1-\gamma_m)E(\alpha_m,\beta_m). \tag{6.24}$$

Figure 4 shows the functions $f_m(r)$ for $m=2,3,\cdots,6$ in the case $\alpha=1/2$.

A spot check for our results is provided by the limit $\alpha \to 2$, corresponding to a flow with a uniform vorticity $4A$. Assuming that $\Lambda_m = 0$ if $m \neq \pm 2$ and that $\Lambda_{\pm 2}$ trace the unit circle in the complex plane, the domain deformation is simply the rotation of a small-eccentricity ellipse with semi-axes $1+2\delta$ and $1-2\delta$. There is an exact analytic solution for such a uniform-vorticity flow in a rotating ellipse; both the direct use of this solution and (6.14) yield the same r-independent value for the leading-order geometric angle that appears for one full rotation of the ellipse, namely $16\pi\delta^2$. See Appendix D for details.

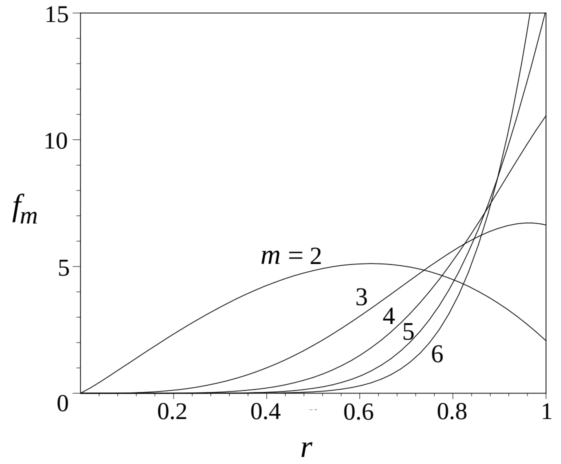

Fig. 4. Functions $f_m(r)$ giving the geometric angle in (6.14) for the axisymmetric flow with streamfunction $\psi_0 = r^{1/2}$ in a disc deformed by a Fourier mode m.

7 Discussion

In this paper, we have used differential geometry mostly as a notational tool, its main application being to make explicit the linear dependence of various quantities on $\dot{\Lambda}$. It is nonetheless clear that the objects we are dealing with can be given an interpretation in a more abstract geometric setting and that the problem may be placed in the framework of geometric mechanics. This would be a valuable undertaking, but one which is probably quite involved due to the infinite-dimensional nature of the problem, and which is certainly beyond the scope of the present paper. However, we now discuss briefly and informally the geometric context of our results in order to elucidate the meanings of the connection one-form $\Phi^\star$, the form of its curvature κ, etc.

Central to our development is the group $G = \mathrm{SDiff}(\mathbb{R}^2)$ of area-preserving diffeomorphisms of the plane. Taking the initial domain D_0 as a reference domain, the subgroup $H \subset G$ which maps D_0 to itself, viz.,

$$H = \{g \in G : gD_0 = D_0\}, \tag{7.1}$$

is of particular importance. In terms of G and H, our parameter space $\mathcal{L}$, the space of all possible shapes Λ of the domain D_Λ, can be realised as the quotient G/H. Indeed, each right coset of H in G contains all diffeomorphisms mapping D_0 to D_Λ for a particular Λ, since any two such diffeomorphisms g and g' are related by $g' = gh$ for some $h \in H$. We can therefore identify $\mathcal{L}$ with G/H. Another important subgroup is

$$H_0 = \{h \in H : \omega_0 \circ h = \omega_0\} \tag{7.2}$$

containing all area-preserving diffeomorphisms in D_0 which leave the initial vorticity distribution invariant. A rearrangement $\omega_0 \circ g$ of the initial vorticity

ω_0 can be identified with an element of G/H_0.

Armed with this setup, we can interpret our results geometrically. The key point is to regard G and G/H_0 as principal bundles, both with $G/H \simeq \mathcal{L}$ as base manifold. Finding the (leading-order) Eulerian flow for each domain shape Λ then amounts to finding a lift from G/H to G/H_0; finding the Lagrangian particle position amounts to finding a lift from G/H to G.[1] Proposition P1, stating that the leading-order Eulerian flow depends only on the domain shape, says that the lift from G/H to G/H_0 is path-independent; in other words, it defines a section of G/H_0.[2] In contrast, the lift from G/H to G, which gives an approximation to the particle position, depends on the path in G/H and in fact on the speed with which the path is traced. There is, however, a contribution that is independent of speed; for cyclic domain deformations, it is quantified by the geometric angle given in P2.

It is worth commenting on the meaning of the one-form $\Phi^\star$ that appears in the geometric angle. One way of defining a lift in a principal bundle is by means of a vector-valued one-form, i.e. a linear map from $T(G/H)$ to TG, describing the vertical (along-fibre) displacement associated with any given displacement on the base manifold G/H. Such a form can be recognised as a connection form. In our context, TG is the space of divergence-free vector fields over $\mathbb{R}^2$, which can be identified through the use of a streamfunction with the space of real-valued functions $\mathcal{C}(\mathbb{R}^2)$. Thus, a lift can be defined by a connection one-form over $G/H \simeq \mathcal{L}$ with values in $\mathcal{C}(\mathbb{R}^2)$. This is precisely the interpretation we give to $\Phi^\star$. With the geometric interpretation of $\Phi^\star$, the subsequent results are clear: (4.26) is the standard expression for the curvature of $\Phi^\star$, the geometric angle (4.27) is given by the holonomy of $\Phi^\star$, and the standard conclusion about the geometrical angle in finite-dimensional systems is recovered.

Throughout the paper, we emphasize that our results are local in nature: the prediction of an instantaneously steady Eulerian flow, for instance, holds only if the domain deformation is such that H1 and H2 are always satisfied. This is necessarily the case if they are satisfied initially and the domain deformation is sufficiently small, but it may well continue to hold for larger deformations. It is nonetheless interesting to speculate about the dynamics when either H1 or H2 fails in the course of the evolution. If H1 fails, the flow ceases to be Arnold stable and likely becomes spectrally unstable. We can then expect the flow to become highly unsteady and, in the absence of dissipative mechanisms, remain so regardless of subsequent deformations of the domain.

---

[1] In our geometric description the interior and exterior of D_Λ are treated on the same footing; this can be done because our formulas, with suitable boundary conditions as $|\boldsymbol{x}| \to \infty$, would also apply to a fluid flow outside D_Λ.

[2] We stress again the local nature of P1: globally, there are many possible steady flows for a given vorticity distribution and a given domain D_Λ. Geometrically, this implies that the section of G/H_0 is multivalued.

The failure of H2, on the other hand, corresponds to the appearance of streamlines for which the orbiting period of particles becomes large. When the period becomes comparable with the time scale of the domain deformation, our asymptotic approach clearly breaks down. This can happen when the flow is driven by the domain deformation towards a change in topology, with the creation of hyperbolic stagnation points and separatrices. How the flow evolves in this situation is unclear, but some understanding could be gained by investigating the problem where the initial steady flow ψ_0 has a hyperbolic stagnation point (and satisfies H1—the Kelvin–Stuart vortex in Holm et al. (1985) is just one example). This problem can be viewed as a generalisation of the classical critical-layer problem for parallel shear flows (e.g., Stewartson (1978); Maslowe (1986) and references therein). In this generalisation, the separatrix plays the role of the zero-velocity critical line (along which H2 is obviously violated); by analogy, it can be expected to be also surrounded by a narrow critical layer where complicated nonlinear dynamics occurs. We plan to investigate this problem in future work.

We conclude this paper by remarking on the possible extension of our results to flows in three dimensions. In three dimensions, the dynamics of an inviscid and incompressible fluid is determined, as in two dimensions, by a form of conservation of vorticity, although in this case it is as a vector that the vorticity is transported (e.g., Arnold and Khesin, 1998). This suggests that our approach for the determination of the leading-order Eulerian flow in deforming domains can be adapted to the three-dimensional setting. The technical conditions for the well-posedness of the equations for g_Λ are however likely to be significantly more complicated than in two dimensions.

The evolution of the fluid-particle position seems, at first sight, to pose a very different problem in three than in two dimensions, since the velocity field is divergence-free and not Hamiltonian. However, particle trajectories for (non-Beltrami) steady solutions of the Euler equations are known to be integrable (Arnold, 1965, 1966) because they are confined to surfaces of constant Bernoulli function (Lamb surfaces). There is, therefore, a simple characterisation of the fluid-particle positions in steady flows, analogous to the action–angle characterisation in two dimensions. This could be used for slowly time-dependent flows to quantify the effects of a cyclic boundary deformation as was done to obtain the geometric angle in this paper.

A general difficulty with three-dimensional flows, however, is the absence of general stability results similar to those obtained by the energy–Casimir method (Holm et al., 1985). Instabilities cannot therefore be excluded (on the contrary, they are the rule rather than the exception), and the effect of their competition with the slow evolution of the leading-order flow would need to be assessed carefully.

A Properties of Φ

In this Appendix, we give details of the derivations of three useful expressions.

1. We first derive (2.38). Applying $\mathbf{d}$ to (2.35) gives

$$\begin{aligned} 0 = \mathbf{d}^2\omega_\Lambda &= -\mathbf{d}[\Phi, \omega_\Lambda] \\ &= -[\mathbf{d}\Phi, \omega_\Lambda] + [\Phi \wedge \mathbf{d}\omega_\Lambda] \\ &= -[\mathbf{d}\Phi, \omega_\Lambda] - [\Phi \wedge [\Phi, \omega_\Lambda]], \end{aligned} \tag{A.1}$$

where the bracket $[\cdot \wedge \cdot]$ is defined in (2.39). Now

$$\begin{aligned} -[\Phi \wedge [\Phi, \omega_\Lambda]] &= -[\Phi_m, [\Phi_n, \omega_\Lambda]]\, \mathbf{d}\Lambda_m \wedge \mathbf{d}\Lambda_n \\ &= \Big\{[\Phi_n, [\omega_\Lambda, \Phi_m]] + [\omega_\Lambda, [\Phi_m, \Phi_n]]\Big\}\, \mathbf{d}\Lambda_m \wedge \mathbf{d}\Lambda_n \\ &= [\Phi \wedge [\Phi, \omega_\Lambda]] + [\omega_\Lambda, [\Phi \wedge \Phi]] \end{aligned} \tag{A.2}$$

(we have used Jacobi's identity, $[f, [g, h]] + [g, [h, f]] + [h, [f, g]] = 0$ for any three functions f, g and h, to arrive at the second equality); therefore

$$-\,[\Phi \wedge [\Phi, \omega_\Lambda]] = \tfrac{1}{2}[\omega_\Lambda, [\Phi \wedge \Phi]] \tag{A.3}$$

and from (A.1) we find

$$\begin{aligned} & [\mathbf{d}\Phi + \tfrac{1}{2}[\Phi \wedge \Phi], \omega_\Lambda] = 0 \\ \Rightarrow \qquad & \mathbf{d}\Phi + \tfrac{1}{2}[\Phi \wedge \Phi] = w \circ \omega_\Lambda \end{aligned} \tag{A.4}$$

for an arbitrary function-valued two-form $w \circ \omega_\Lambda$.

2. Next we show that (A.4) can be derived directly from (2.40). This provides a consistency check for our developments. Let us first compute

$$\begin{aligned} \mathbf{d}\,[\Phi, \psi_\Lambda] &= \mathbf{d}\Big\{[\Phi_m, \psi_\Lambda]\, \mathbf{d}\Lambda_m\Big\} \\ &= [\mathbf{d}\Phi_m, \psi_\Lambda] \wedge \mathbf{d}\Lambda_m + [\Phi_m, \mathbf{d}\psi_\Lambda] \wedge \mathbf{d}\Lambda_m \\ &= [\mathbf{d}\Phi, \psi_\Lambda] - [\Phi \wedge \mathbf{d}\psi_\Lambda] \end{aligned} \tag{A.5}$$

and

$$\begin{aligned}\mathbf{d}(\mathbf{d}G_\Lambda \circ \omega_\Lambda) &= -(\mathbf{d}G'_\Lambda \circ \omega_\Lambda) \wedge \mathbf{d}\omega_\Lambda = (\mathbf{d}G'_\Lambda \circ \omega_\Lambda) \wedge [\Phi, \omega_\Lambda] \\ &= [\Phi \wedge \mathbf{d}G_\Lambda],\end{aligned} \tag{A.6}$$

where the last equality can be verified by computation in coordinates.

Writing (2.40) as

$$\Delta\,[\Phi, \psi_\Lambda] - [\Phi, \omega_\Lambda] - \Delta(\mathbf{d}G_\Lambda \circ \omega_\Lambda) = 0 \tag{A.7}$$

and taking $\mathbf{d}$, we find

$$\begin{aligned}0 &= \Delta\,\mathbf{d}[\Phi, \psi_\Lambda] - \mathbf{d}[\Phi, \omega_\Lambda] - \Delta\mathbf{d}(\mathbf{d}G_\Lambda \circ \omega_\Lambda) \\ &= \Delta[\mathbf{d}\Phi, \psi_\Lambda] - \Delta[\Phi \wedge \mathbf{d}\psi_\Lambda] - [\mathbf{d}\Phi, \omega_\Lambda] + [\Phi \wedge \mathbf{d}\omega_\Lambda] + \Delta[\Phi \wedge \mathbf{d}G_\Lambda] \\ &= (\Delta - F'_\Lambda)\,[\mathbf{d}\Phi, \psi_\Lambda] + \Delta\,[\Phi \wedge (\mathbf{d}G_\Lambda - \mathbf{d}\psi_\Lambda)] + [\Phi \wedge \mathbf{d}\omega_\Lambda] \\ &= (\Delta - F'_\Lambda)\,[\mathbf{d}\Phi + \tfrac{1}{2}[\Phi \wedge \Phi], \psi_\Lambda].\end{aligned} \tag{A.8}$$

A couple of identities have been used to arrive at the last equation. The first one is

$$[\Phi \wedge [\Phi, \psi_\Lambda]] = \tfrac{1}{2}\,[[\Phi \wedge \Phi], \psi_\Lambda], \tag{A.9}$$

which is proved in the same way as (A.3). The second identity is

$$\begin{aligned}[\Phi \wedge \mathbf{d}\omega_\Lambda] &= [\Phi \wedge [\Phi, F_\Lambda \circ \psi_\Lambda]] = [\Phi \wedge F'_\Lambda[\Phi, \psi_\Lambda]] \\ &= F'_\Lambda[\Phi \wedge [\Phi, \psi_\Lambda]] - [\Phi, F'_\Lambda] \wedge [\Phi, \psi_\Lambda] = F'_\Lambda[\Phi \wedge [\Phi, \psi_\Lambda]],\end{aligned} \tag{A.10}$$

where we have used $[\Phi, F'_\Lambda \circ \psi_\Lambda] \wedge [\Phi, \psi_\Lambda] = F''_\Lambda\,[\Phi, \psi_\Lambda] \wedge [\Phi, \psi_\Lambda] = 0$ for the last equality.

The desired result (A.4) is recovered by noting that the operator $(\Delta - F'_\Lambda)$ is invertible by hypothesis and that $[\mathbf{d}\Phi + \frac{1}{2}[\Phi \wedge \Phi], \psi_\Lambda] = 0$ on ∂D_Λ. The latter can be verified by differentiating (2.35) and evaluating it on ∂D_Λ.

3. Finally, we establish the formula

$$\mathbf{d}\hat{\Phi} - \tfrac{1}{2}[\hat{\Phi} \wedge \hat{\Phi}] = \mathbf{d}\Phi + \tfrac{1}{2}[\Phi \wedge \Phi]. \tag{A.11}$$

Its application to the natural connection $\Phi^\star$ shows that κ is independent of θ. Our proof starts by noticing that $[\hat{\Phi} \wedge \hat{\Phi}] = [\Phi \wedge \Phi]$ because the transformation to action–angle variables is canonical. Thus (A.11) is equivalent to

$$\mathbf{d}\hat{\Phi} = \mathbf{d}\Phi + [\Phi \wedge \Phi]. \tag{A.12}$$

This is established by direct computation as follows

$$\begin{aligned}
\mathbf{d}\hat{\Phi}(I,\theta;\Lambda) &= \mathbf{d}\Phi(\boldsymbol{X}(I,\theta;\Lambda);\Lambda)\\
&= \mathbf{d}\Phi(\boldsymbol{x};\Lambda) + \sum_n \Big(\mathbf{d}\boldsymbol{X}\cdot\nabla\Phi_n\Big)\Big|_{(\boldsymbol{x},\Lambda)}\mathbf{d}\Lambda_n\\
&= \mathbf{d}\Phi(\boldsymbol{x};\Lambda) + \sum_{m,n}[\Phi_m,\Phi_n]\Big|_{(\boldsymbol{x},\Lambda)}\mathbf{d}\Lambda_m\wedge\mathbf{d}\Lambda_n\\
&= \mathbf{d}\Phi(\boldsymbol{x};\Lambda) + [\Phi\wedge\Phi]\Big|_{(\boldsymbol{x},\Lambda)}.
\end{aligned} \tag{A.13}$$

B Solution of $(\Delta - F'_\Lambda \mathsf{P}_\Lambda)\, u = f$

Here we show that the problem

$$\begin{aligned}
&(\Delta - F'_\Lambda\, \mathsf{P}_\Lambda)\,\eta = f\\
&\eta = g \qquad \text{on } \partial D_\Lambda
\end{aligned} \tag{B.1}$$

has a unique solution η when $F'_\Lambda > -c_{\rm poi}$ everywhere in D_Λ as follows from the hypothesis H1.

We start with an identity. Let u and v be such that $\mathsf{P}_\Lambda u = 0$ and $\mathsf{P}_\Lambda v = v$. We have

$$\int_D u\,v\;\mathrm{d}x\,\mathrm{d}y = \int\Big\{\oint u\,v\;\mathrm{d}s\Big\}\,\mathrm{d}\psi_\Lambda = \int u\,\Big\{\oint v\;\mathrm{d}s\Big\}\,\mathrm{d}\psi_\Lambda = 0. \tag{B.2}$$

From this it follows that the projection P_Λ is orthogonal in $L^2(D_\Lambda)$, in the sense that for any (sufficiently smooth) function w

$$\begin{aligned}
\int_D |w|^2\;\mathrm{d}x\,\mathrm{d}y &= \int_D \Big\{|\mathsf{P}_\Lambda w|^2 + 2(\mathsf{P}_\Lambda w)[(1-\mathsf{P}_\Lambda)w] + |(1-\mathsf{P}_\Lambda)w|^2\Big\}\;\mathrm{d}x\,\mathrm{d}y\\
&= \int_D \Big\{|\mathsf{P}_\Lambda w|^2 + |(1-\mathsf{P}_\Lambda)w|^2\Big\}\;\mathrm{d}x\,\mathrm{d}y.
\end{aligned} \tag{B.3}$$

Using (B.2), we find that the operator $(\Delta - F'_\Lambda\,\mathsf{P}_\Lambda)$ is self-adjoint for any functions u and v which vanish on ∂D,

$$\int_D v\,(\Delta - F'_\Lambda\,\mathsf{P}_\Lambda)\,u\;\mathrm{d}x\,\mathrm{d}y = \int_D u\,(\Delta - F'_\Lambda\,\mathsf{P}_\Lambda)\,v\;\mathrm{d}x\,\mathrm{d}y. \tag{B.4}$$

Moreover, $(\Delta - F'_\Lambda\,\mathsf{P}_\Lambda)$ is coercive under the hypothesis $F' > -c_{\rm poi}$. To show this, we first combine (B.3) and Poincaré inequality to obtain

$$\int_D |\mathsf{P}_\Lambda u|^2\;\mathrm{d}x\,\mathrm{d}y \le \int_D |u|^2\;\mathrm{d}x\,\mathrm{d}y \le \frac{1}{c_{\rm poi}}\int_D |\boldsymbol{\nabla} u|^2\;\mathrm{d}x\,\mathrm{d}y \tag{B.5}$$

for any function u vanishing on ∂D. It is then clear that

$$\int_D u\,(\Delta - F_\Lambda' \,\mathsf{P}_\Lambda)\, u \,\mathrm{d}x\,\mathrm{d}y = -\int_D \Big\{ |\boldsymbol{\nabla} u|^2 + F_\Lambda' (\mathsf{P}_\Lambda u)^2 \Big\} \,\mathrm{d}x\,\mathrm{d}y \le 0 \qquad \text{(B.6)}$$

when $F_\Lambda' > c_{\mathrm{poi}}$ everywhere in D, with equality obtaining only when $u = 0$.

Returning to the problem (B.1), we extend g to $\mathrm{cl}\, D_\Lambda$ and let $\tilde\eta = \eta - g$. The problem thus becomes

$$(\Delta - F_\Lambda' \mathsf{P}_\Lambda)\,\tilde\eta = -\Delta g + F_\Lambda' \mathsf{P}_\Lambda g \qquad \text{(B.7)}$$

with boundary conditions $\tilde\eta = 0$ on ∂D_Λ. We have shown that the operator $(\Delta - F_\Lambda' \mathsf{P}_\Lambda)$ on the left-hand side is self-adjoint and its associated bilinear form is coercive, so by the Lax–Milgram lemma (assuming compactness, etc., cf. Gilbarg and Trudinger (1977)) a unique solution η exists for (B.1).

C Second-order terms in nearly axisymmetric flows

At order $O(\delta^2)$, ρ_2 is found from (5.8) to satisfy

$$\begin{aligned} \frac{\psi_0'}{r}\Delta\partial_\sigma\rho_2 + 2\Big(\frac{\psi_0'}{r}\Big)'\Big(\partial^2_{r\sigma}\rho_2 - \frac{1}{r}\partial_\sigma\rho_2\Big) + \frac{2}{r}\,(r\chi_2')' \\ = 2[\rho_1, \Delta[\rho_1,\psi_0]] - [\rho_1,[\rho_1,\Delta\psi_0]] - \Delta[\rho_1,[\rho_1,\psi_0]]. \end{aligned} \qquad \text{(C.1)}$$

The boundary condition (5.11) can be written as

$$\partial_\sigma\rho_2 = \partial_\sigma\left(\partial_r\rho_1\partial_\sigma\rho_1\right) - \left(\partial_\sigma\rho_1\right)^2 + \sum_m |\Lambda_m|^2 \quad \text{at } r = 1, \qquad \text{(C.2)}$$

after some manipulations. The interest of this form is that, when (6.7) is taken into account, it is clearly consistent, with both sides having a vanishing σ-average. A solvability condition for (C.1) is obtained by averaging over σ, leading to

$$(r\chi_2')' = -\Big(\frac{\psi_0'}{2\pi r}\int_0^{2\pi}\Big[(\partial^2_{r\sigma}\rho_1)^2 + \frac{1}{r^2}(\partial^2_{\sigma\sigma}\rho_1)^2 - \frac{2}{r}\partial_\sigma\rho_1\partial^2_{r\sigma}\rho_1\Big]\,\mathrm{d}\sigma\Big)'.$$

This equation determines χ_2 uniquely up to an irrelevant arbitrary constant. When it is satisfied, (C.1) can be solved for ρ_2, yielding a solution in the form of a Fourier series

$$\rho_2(r,\sigma) = \sum_m \hat\rho_{2,m}(r)\,\mathrm{e}^{\imath m\sigma},$$

with $\hat\rho^*_{2,m} = \hat\rho_{2,-m}$ and $\hat\rho_{2,0} = 0$. The functions $\hat\rho_{2,m}$ satisfy an inhomogeneous version of (6.6) obtained from (C.2); clearly, they are quadratic in the Λ_m.

D Rotating ellipse

Consider a fluid inside an ellipse with semi-axes a and b that is rotating around its centre with a (possibly time-dependent) angular velocity $\varepsilon\dot{\lambda}(\tau)$. The equation of the ellipse is given by

$$B(x,\tau) = \frac{\hat{x}_1^2}{a^2} + \frac{\hat{x}_2^2}{b^2} - 1 = 0,$$

where

$$\begin{aligned} \hat{x}_1 &= x\cos\lambda + y\sin\lambda, \\ \hat{x}_2 &= -x\sin\lambda + y\cos\lambda \end{aligned}$$

are Cartesian coordinates in a frame rotating with angular velocity $\varepsilon\dot{\lambda}$. An exact solution for the fluid motion in such a rotating ellipse is provided by the uniform-vorticity flow with streamfunction

$$\psi(\boldsymbol{x},t) = K\left(\frac{\hat{x}_1^2}{a^2} + \frac{\hat{x}_2^2}{b^2}\right) + \frac{\varepsilon\dot{\lambda}(a^2-b^2)}{2(a^2+b^2)}\left(\hat{x}_1^2 - \hat{x}_2^2\right),$$

where K is a constant. In this streamfunction, which can be verified directly to satisfy the boundary condition (2.4), the first term can be identified with $\psi^{(0)}$, the second with $\psi^{(1)}$, and there are no higher-order terms in ε (see, e.g., Jeffreys and Jeffreys, 1974, p. 421, for a derivation). Action–angle coordinates (I,θ) for this flow satisfy

$$\begin{aligned} \hat{x}_1 &= \sqrt{2Ia/b}\,\cos\theta, \\ \hat{x}_2 &= \sqrt{2Ib/a}\,\sin\theta. \end{aligned}$$

In terms of these variables, the streamfunction, or Hamiltonian, becomes

$$\hat{H}(I,\theta) = \frac{2KI}{ab} + \frac{\varepsilon\dot{\lambda}I}{ab}\left[\frac{a^2-b^2}{a^2+b^2}(a^2\cos^2\theta - b^2\sin^2\theta) - (a^2\cos^2\theta + b^2\sin^2\theta)\right]. \tag{D.1}$$

In this expression, the last term between round brackets comes from the time-dependence in the (canonical) transformation from (x,y) to (I,θ); it simply corresponds to a rigid-body rotation with angular velocity $-\varepsilon\dot{\lambda}$. The geometric angle is derived by writing the evolution equation for θ, averaging, then integrating in time. This gives

$$\Delta\theta_{\text{geo}} = \frac{\Delta\lambda}{2ab}\left[\frac{(a^2-b^2)^2}{a^2+b^2} - (a^2+b^2)\right], \tag{D.2}$$

where $\Delta\lambda$ is the total angle rotated by the ellipse.

Note that the averaging is in fact unnecessary, since the Hamiltonian $\hat{H}$ does not depend on θ as a simplification of (D.1) indicates. We do not perform this simplification here, however, in order to retain the two terms in (D.2) separately. This facilitates the comparison with the general formalism of §4. The first term in (D.2) stems from the correction in the streamfunction $\psi^{(1)}$ (which here corresponds to a potential flow), while the second stems from the slow time-dependence of the leading-order flow; thus these two terms can be identified with the two contributions $\langle \mathbf{d}\hat{\Phi}^\star \rangle$ and $-\frac{1}{2}\langle [\hat{\Phi}^\star \wedge \hat{\Phi}^\star] \rangle$ in (4.25).

We can use the exact formula (D.2) to verify the approximate results for slightly deformed axisymmetric flows obtained in §6. A rotating ellipse of small eccentricity is represented by the deformed disc (6.1) with $\Lambda_{\pm 2}(\tau)$ describing a unit circle in the complex plane and all the other Λ_m equal to zero. The corresponding semi-axes are then

$$a = 1 + 2\delta + O(\delta^2) \quad \text{and} \quad b = 1 - 2\delta + O(\delta^2),$$

with the $O(\delta^2)$ corrections ensuring that $ab = 1$. Introducing this into (D.2) and considering a full rotation $\Delta\lambda = 2\pi$ gives the geometric angle

$$\Delta\theta_{\mathrm{geo}} = \pi \left[32\delta^2 - (2 + 16\delta^2) \right] + O(\delta^3) = -2\pi + 16\pi\delta^2 + O(\delta^3). \tag{D.3}$$

An equivalent result is obtained from the developments in §6. Since the only non-zero parameter Λ_m is $\Lambda_{\pm 2}$, (6.14) reduces to

$$\Delta\theta_{\mathrm{geo}} = \delta^2 f_2(r) \mathcal{A}_2 + O(\delta^3).$$

The uniform-vorticity corresponds to the limit $\alpha \to 2$ in (6.15), so that $\alpha_2 = \beta_2 = 2$, $\gamma_2 = 1/2$, and $f_2(r) = 8$, independent of r. Because a full rotation of the ellipse is obtained when $\Lambda_2(\tau)$ covers twice the unit circle, $\mathcal{A}_2 = 2\pi$ and hence

$$\Delta\theta_{\mathrm{geo}} = 16\pi\delta^2 + O(\delta^3),$$

with contributions $32\pi\delta^2$ and $-16\pi\delta^2$ from $\langle \mathbf{d}\hat{\Phi}^* \rangle$ and $-\frac{1}{2}\langle [\hat{\Phi}^*, \hat{\Phi}^*] \rangle$, respectively. The discrepancy of -2π when compared with (D.3) results from a different definition of the angle θ, which is measured from an axis rotating with the ellipse in the calculation leading to (D.3) while it is measured from a fixed axis in §6.
